

1 Erosion of somatic tissue identity with loss of the X-linked intellectual 2 disability factor KDM5C

3
4 Gaps in knowledge addressed: * Are other tissue-enriched genes dysregulated, or only testis, germline genes? * Curating
5 a robust list of male and female germline genes * Should talk about 2-cell genes vs germline genes - way to systematically
6 categorize? * Mechanism behind long-term germline gene misexpression * Recent evidence suggests loss of KDM5C
7 in ESCs express some germline genes * Unclear if catalytic activity is required for long-term silencing * Unclear if their
8 dysregulation lasts throughout life or the same between brain or not * When in development does it begin? - Recent evidence
9 suggests some germline genes expressed in 5CKO ESCs but unclear if their dysregulation lasts throughout differentiation
10 and if the identity of germline genes are different compared to the brain * Are there functional consequences to germline
11 gene misexpression?

12 Introduction: * Chromatin regulators are important for cellular identity * H3K4me1-3 linked to active gene promoters and
13 enhancers * Surprisingly, mutations in Chromatin regulators lead to many NDDs (including many H3K4 regulators) * Recent
14 studies have shown some chromatin regulators are important for regulating neuron-specific gene expression/chromatin
15 stat_compare_means * However, loss of some chromatin regulators can also lead to ectopic expression of tissue-enriched
16 genes * Very few studies have looked at these genes and it's unclear if these genes contribute to NDD impairments. *
17 Necessary to first characterize the mechanism behind their derepression to identify molecular footholds into testing their
18 contribution to neuronal impairments and potential for therapeutic intervention

- 19 • Loss of KDM5C can result in the misexpression of genes typically only found in the testis
20 – Misexpression of tissue-enriched genes hasn't been systematically characterized - Unclear if these genes are
21 exceptions or if other tissue-specific genes are dysregulated
22 – Interestingly, these genes (Cyct, D1pas1) typically function in the germline
23 – Germ cells (meiotic cells) are typically distinguished from somatic cells very early on in embryogenesis and is a
24 key feature of multicellularity
25 – Chromatin regulators are very important for decommissioning germline genes and act successively the embryo
26 implants into the uterine wall
27 * Most studies have focused on ESCs, which have a similar transcriptome to germ cells / 2-cells
28 * recently, KDM5C was shown to repress DAZL in ESCs, independent of its catalytic activity
29 * However, DNA methylation is lost in the mature 5CKO brain, DNA methylation is placed later and it's unclear if
30 it's required for long-term repression (maybe too specific, just trying to go into the fact that the mechanism is
31 partially understood but unclear)
32 – Systematic characterization of ectopic germline genes hasn't been done
33 * unknown if other germline-enriched genes are dysregulated, including oocyte-specific genes
34 * Crucially, it's unknown if misexpression of the germline program leads to functional consequences in 5CKO
35 cells.

36 Introduction

37 To form a complete organism, embryonic stem cells must differentiate into a myriad of discrete cellular identities. This is
38 in part accomplished by chromatin regulators that can either promote or impede lineage-specific gene expression through
39 histone and DNA modifications^{1,2}. Although initially identified for their roles in cellular identity^{3,4}, recent advancements in
40 next generation sequencing technologies unexpectedly found many neurodevelopmental disorders (NDDs) are caused by or
41 linked to mutations in chromatin regulators. This relationship is partially explained by their regulation of brain-specific genes
42 or chromatin states, such as modulating genes involved in synaptic maturation⁵ or the transition between neuronal and glial
43 developmental programs⁶. However, loss of some chromatin regulators can also lead to the misexpression of tissue-specific
44 genes outside of their intended environment^{3,4,7}. Currently, very few studies have explored the misexpression of non-neuronal,
45 tissue-specific genes in chromatin-linked neurodevelopmental disorders^{8,9} and it is unclear if this partial loss of brain identity
46 contributes to neurodevelopmental impairments. To elucidate their contribution to neurodevelopmental impairments, it is
47 essential to first characterize the types of genes misexpressed, the developmental time point the dysregulation begins, and
48 the molecular mechanism underlying their de-repression. Characterizing these features will enable us to identify molecular
49 footholds common between NDDs that can then be exploited for potential therapeutics.

50 In this study, we characterized the misexpression of tissue-enriched genes with loss of the chromatin regulator lysine
51 demethylase 5C (KDM5C, also known as SMCX or JARID1C), a histone 3 lysine 4 demethylase. Pathogenic mutations in
52 *KDM5C* cause Intellectual Developmental Disorder, X-linked, Syndromic, Claes-Jensen Type (MRXSCJ, OMIM: 300534),
53 whose features include short stature, intellectual disability, seizures, aberrant aggression, and autistic behaviors^{10–12}. Previous
54 work has demonstrated constitutive *Kdm5c* knockout (-KO) mice recapitulate key MRXSCJ patient phenotypes, including
55 hyperaggression and learning impairments¹³. Next generation RNA sequencing (RNA-seq) in the *Kdm5c*-KO hippocampus
56 surprisingly revealed ectopic expression of testis-enriched genes within the brain⁹. However, it is currently unclear if
57 misexpression in the *Kdm5c*-KO brain is unique to testis genes, as other tissue-enriched genes have not been systematically
58 evaluated.

59 Interestingly, some of the ectopic testis transcripts identified in the *Kdm5c*-KO brain are typically expressed in germ cells⁹.
60 Unlike somatic cells, germ cells (e.g. sperm and eggs) undergo meiosis and pass on their genetic material to the next genera-
61 tion. The germline and the soma are typically distinguished during early embryogenesis, when germline genes are silenced
62 in epiblast stem cells soon after implantation and only reactivated in a subset to form the germline. Chromatin regulators
63 play a key role in decommissioning germline genes as the embryo transitions from naive to primed pluripotency by placing
64 repressive histone H2A lysine 119 monoubiquitination (H2AK119ub1)¹⁴, histone 3 lysine 9 trimethylation (H3K9me3)^{14,15},
65 and DNA CpG methylation^{15–17} at germline gene promoters. KDM5C may also be involved in this early decommissioning of
66 germline genes, as re-expression of KDM5C in neurons fails to suppress their dysregulation⁹. In support of this, KDM5C
67 was very recently shown to repress *Deleted in azoospermia like (Dazl)*, a key regulator of germline development, in mouse
68 embryonic stem cells (ESCs)^{18,19}. In support of this, two independent screens in mouse embryonic stem cells (ESCs) recently
69 identified KDM5C as a repressor of *Deleted in azoospermia like (Dazl)*, a key regulator of germline development. However,
70 KDM5C's role in embryonic germline gene repression is currently unclear, given that Dazl is also expressed in ESCs and in
71 the 2-cell stage and germline gene misexpression has yet to be globally characterized during *Kdm5c*-KO embryogenesis.

72 To elucidate KDM5C's role in tissue identity, here we characterized the aberrant transcription of tissue-enriched genes
73 within the *Kdm5c*-KO brain and epiblast-like cells (EpiLCs), an *in vitro* model of the post-implantation embryo. We identified
74 widespread dysregulation of tissue-enriched genes in both the adult *Kdm5c*-KO brain and EpiLCs, including misexpression

75 of liver, muscle, and ovary genes. The *Kdm5c*-KO amygdala and hippocampus had significant enrichment of testis-biased
76 genes that are unique to germ cells. To better characterize germline gene misexpression, we then generated a dataset of
77 germline-enriched genes by comparing gene expression in gonads with germ cell depletion. We found *Kdm5c*-KO EpiLCs
78 primarily expressed unique germline genes compared to the mature *Kdm5c*-KO brain, including *Dazl* and *Stra8*, key drivers
79 of germline identity and meiosis. While KDM5C is directly bound to some germline gene promoters in EpiLCs, it is not directly
80 bound to many germline-enriched mRNAs expressed with *Kdm5c*-KO cells, indicating germline genes can be aberrantly
81 transcribed through indirect mechanisms. Finally, we found KDM5C loss impairs the placement of DNA methylation at
82 germline gene promoters as ESCs differentiate into EpiLCs. Therefore, we propose KDM5C plays a crucial role in the
83 development of tissue identity during early embryogenesis, including establishment of the soma-germline boundary.

84 **note: need a better conclusion sentence - work on when we know what's happening with last figure/functional
85 consequences**

86 Results

87 **Tissue-enriched genes, including testis genes, are aberrantly expressed in the *Kdm5c*-KO brain**

88 • **note: should I compare amygdala and hippocampus? scandaglia only looked at hippocampus**

89 A previous RNA sequencing (RNA-seq) study surprisingly revealed the aberrant expression of testis genes within the adult
90 *Kdm5c* knockout (-KO) hippocampus⁹. Given the high abundance of testis-enriched genes within the mouse transcriptome, it
91 is currently unclear if their misexpression in the *Kdm5c*-KO brain is indicative of random de-repression throughout the genome
92 or instead reflects an impairment in tissue identity. To distinguish these possibilities, we globally assessed the expression of
93 previously characterized tissue-enriched genes²⁰ in our previously published mRNA-seq datasets of the *Kdm5c*-KO amygdala
94 and hippocampus²¹.

95 We found many genes significantly upregulated within the *Kdm5c*-KO brain (DESeq2²², log2 fold change > 0.5, q < 0.1)
96 are typically enriched in non-brain tissues, with the majority of differentially expressed genes (DEGs) displaying biased
97 expression towards the testis (Figure 1A-C). Even though the testis has the largest number of tissue-biased genes compared
98 to any other tissue (2,496 genes), testis-biased DEGs were significantly enriched for both brain regions (Amygdala p =
99 1.83e-05; Hippocampus p = 4.26e-11, Fisher's Exact).

100 Even though the *Kdm5c*-KO mice are male, we also observed significant enrichment of ovary-biased DEGs within both
101 brain regions (Amygdala p = 0.00574; Hippocampus p = 0.048, Fisher's Exact) (Figure 1D). Intriguingly, many ovary and
102 testis-biased DEGs have functions specific to germ cells and have no known role in the brain. For example, the testis-biased
103 DEG *Cytochrome C, testis* (*Cyct*) is a testis-specific cytochrome c isoform found in spermatozoa mitochondria and is important
104 for flagellar beating^{23,24} (Figure 1C). The ovary-enriched DEG *Zygotic arrest 1* (*Zar1*) was recently shown to sequester
105 mRNAs in oocytes for meiotic maturation and early zygote development²⁵ (Figure 1D). Although not consistent across brain
106 regions, we also found enrichment of two non-gonadal tissues - the liver (Amygdala p = 0.0398, Fisher's Exact) and the
107 muscle (Hippocampus p = 0.0104, Fisher's Exact). One example of a liver-biased DEG is *Apolipoprotein C-I* (*Apoc1*), which
108 is involved in lipoprotein metabolism (Figure 1E). Overall, these tissue-enriched genes show little to no expression in the
109 wild-type brain, yet our mRNA-seq data indicate they are polyadenylated and spliced into mature transcripts (Figure 1C-E).

110 Of note, we did not observe enrichment of brain-enriched genes (Amygdala p = 1; Hippocampus p = 0.74, Fisher's
111 Exact), even though the brain has the second highest total number of tissue-enriched genes (708 genes). Altogether, these

112 results suggest misexpression of testis and other tissue-enriched genes within the *Kdm5c*-KO brain is not due to random
113 de-repression of all genes, but rather due to a dysregulation of tissue identity.

114 **Germline genes are aberrantly expressed in the male *Kdm5c*-KO brain**

115 The testis contains both germ cells (e.g. spermatogonia) and somatic cells (e.g. Leydig cells) that support hormone
116 production and germline functions. We then wondered if the high enrichment of testis genes in the *Kdm5c*-KO brain reflected
117 a failure to demarcate between the soma and germline. Gene ontology analysis of testis-biased DEGs revealed enrichment
118 of germline-relevant ontologies, including spermatid development (GO:0,007,286, p.adjust = 6.2e-12) and sperm axoneme
119 assembly (GO:0,007,288, p.adjust = 2.45e-14) (Figure 2A).

120 To further validate if these testis DEGs are truly germline genes, we then compared their expression in a published
121 RNA-seq dataset of wild-type (WT) and germ cell-depleted (*Kit*^{W/W^v}) mouse testes²⁶. We found almost all *Kdm5c*-KO
122 testis-enriched DEGs lose their expression with germ cell depletion (Figure 2B). The only testis DEG that did not show
123 considerable downregulation with germline depletion was *FK506 binding protein 6* (*Fkbp6*), a known regulator of piRNA
124 expression and meiosis in germ cells^{27,28}. We additionally assessed testis DEG expression in a published testis single cell
125 RNA-seq dataset that identified cell type-specific markers²⁹. We found that while some testis-enriched DEGs were classified
126 as specific markers for different germ cell types (e.g. spermatogonia, spermatocytes, round spermatids, and elongating
127 spermatids) none marked somatic cells (Figure 2C). Together, these data suggest the *Kdm5c*-KO brain expresses germline
128 genes.

129 We then aimed to globally characterize germline gene misexpression in *Kdm5c*-KO mice, but lacked a comprehensive list
130 of mouse germline-enriched genes. To facilitate downstream analyses, we generated a list of male and female germline-
131 enriched genes by evaluating gene expression in wild-type and germline-depleted (*Kit*^{W/W^v}) mice. We assessed gene
132 expression in male and female mice at embryonic day 12, 14, and 16, as well as male postnatal day 6 and adult testes. We
133 defined genes as germline-enriched if their expression met the following criteria: 1) their expression is greater than 1 FPKM
134 in wild-type germline 2) their expression in any wild-type, non-gonadal tissue²⁰ does not exceed 20% of maximum expression
135 in wild-type germline, and 3) their expression in the germ cell-depleted germline, for any sex or time point, does not exceed
136 20% of their maximum expression in the wild-type germline. These criteria yielded 1,287 germline-enriched genes.

137 ***Kdm5c*-KO epiblast-like cells aberrantly express master regulators of germline identity**

138 Misexpression of germline genes in the *Kdm5c*-KO brain suggests mutants fail to demarcate germline and somatic cellular
139 identity. Germ cells are typically distinguished from somatic cells soon after the embryo implants into the uterine wall^{30,31}
140 when a subset of epiblast stem cells become the primordial germ cells (PGCs) while the remainder differentiate into the
141 ectoderm, mesoderm, and endoderm to form the body's somatic tissues³². This developmental time point can be modeled *in*
142 *vitro* through differentiation of embryonic stem cells (ESCs) into post-implantation epiblast-like stem cells (EpiLCs) (Figure
143 3A, top). Previous studies have demonstrated that while some germline-enriched genes are also expressed in embryonic
144 stem cells (ESCs), they are silenced as they differentiate into EpiLCs¹⁵. Therefore, we assessed if KDM5C was necessary
145 for initial germline gene silencing by assessing their expression in male *Kdm5c*-KO EpiLCs using our previously generated
146 RNA-seq dataset³³.

147 We did not observe any apparent morphology changes between wild-type and *Kdm5c*-KO cells during ESC to EpiLC
148 differentiation (Figure 3A, bottom) and found no significant difference in primed pluripotency genes that indicate proper EpiLC

149 differentiation (Figure 3B). We then identified *Kdm5c*-KO EpiLC DEGs through DESeq2²² (log2 fold change > 0.5, q < 0.1)
150 and again observed widespread dysregulation of tissue-enriched genes, with the largest number of genes belonging to the
151 brain and testis, although they were not significantly enriched (Figure 3C).

152 Using our curated list, we found 54 germline-enriched genes were misexpressed in *Kdm5c*-KO EpiLCs, including *Cyct*
153 (Figure 3D). To evaluate whether germline mRNAs are constitutively dysregulated or change over the course of development,
154 we then compared EpiLC germline DEGs to those expressed in the *Kdm5c*-KO brain. The majority of EpiLC germline DEGs
155 were unique to EpiLCs, with only *Cyct* shared across sequencing datasets (Figure 3E).

156 We then compared the function of EpiLC and brain germline DEGs through gene ontology and found particularly high
157 enrichment of meiosis-related gene ontologies in EpiLCs (Figure 3F), such as meiotic cell cycle (GO:0,051,321, p.adjust =
158 4.44e-07). While a few meiosis-related genes are misexpressed in the *Kdm5c*-KO brain, DEGs unique to *Kdm5c*-KO EpiLCs
159 included master regulators of germline identity, such as *Stimulated by retinoic acid 8 (Stra8)* and *Deleted in azoospermia*
160 *like (Dazl)* (Figure 3G). These genes are typically expressed during embryonic germ cell development to commit PGCs
161 to the germline fate, but are also expressed later in life to trigger meiotic gene expression programs³⁴⁻³⁶. Of note, some
162 germline genes, including *Dazl*, are also expressed in the two-cell embryo. However, we did not see misexpression of two-cell
163 embryo-specific genes, like *Zscan4d* (q = 0.381).

164 *Dazl* is an RNA-binding protein that regulates the translation of germline mRNAs and is essential for germ cell function³⁷.
165 Interestingly, a significant portion of germline transcripts expressed in *Kdm5c*-KO EpiLCs are known binding targets of
166 DAZL, including *Stra8*³⁸ (p = 1.698e-07, Fisher's Exact Test). This suggests expression of DAZL protein would enable
167 the translation of other aberrant germline transcripts, influencing their ability to impact on *Kdm5c*-KO cellular function. We
168 therefore stained *Kdm5c*-KO EpiLCs for DAZL protein expression through immunocytochemistry (Figure 3H). We found
169 about 25% of *Kdm5c*-KO EpiLCs expressed DAZL protein in their cytoplasm (p = 0.0015, Welch's t-test), consistent with the
170 subcellular localization observed when DAZL is stained in spermatogonia³⁸. Altogether these results suggest *Kdm5c*-KO
171 EpiLCs fail to decommission germline genes during early embryogenesis, including master regulators of germline identity
172 that can be translated into protein.

173 KDM5C-mediated removal of H3K4me3 during early embryogenesis promotes long-term repression of germline 174 genes

175 **Figure 4: Loss of KDM5C's catalytic activity impairs DNAm placement and long-term silencing of germline genes**

186

187 Direct vs indirect binding motif analysis

188 Previous work suggests KDM5C represses germline genes during early development, since KDM5C binding is gradually
189 lost at hippocampal germline DEG promoters over development⁹ and re-expression of KDM5C in neuronal cultures fails to
190 suppress their transcription. However, we identified many germline genes that were only dysregulated in *Kdm5c*-KO EpiLCs
191 and not in the mature brain, including master regulators of meiosis and germline identity. While KDM5C was recently shown
192 to bind to *Dazl* in ESCs^{18,19}, it's unclear if KDM5C binds to other master regulators that are expressed in *Kdm5c*-KO EpiLCs
193 and if this binding is maintained as cells differentiate.

194 To better elucidate the mechanism behind KDM5C-mediated germline gene silencing, we analyzed KDM5C chromatin
195 immunoprecipitation followed by DNA sequencing (ChIP-seq) datasets we previously generated in EpiLCs³³ and primary
196 hippocampal and cortical neuron cultures (PNCs)¹³. We identified a higher number of KDM5C peaks in EpiLCs overall
197 (EpiLCs: 2,437, PNCs: 1,610, MACS2 q < 0.1 and fold enrichment > 1) and while KDM5C was primarily localized to gene
198 promoters in both cell types (EpiLCs: , PNCs: , +/- kb TSS), PNCs showed increased localization to distal intergenic regions
199 (EpiLCs: , PNCs:) (Figure 4A). Gene ontology analysis of KDM5C-bound promoters in EpiLCs revealed high enrichment
200 of germline-related ontologies, including meiotic nuclear division (GO:0140013) and synaptonemal complex assembly
201 (GO:0007130) (Figure 4B). Contrastingly, germline ontologies are not enriched in PNCs and KDM5C-bound genes instead
202 perform non-germline-specific functions, such as heterocycle synthesis (GO: 0018130) and pyrimidine metabolism (GO:
203 0072527).

204 We then assessed KDM5C binding at germline genes expressed *Kdm5c*-KO cells to assess if their dysregulation is due to
205 direct loss of KDM5C binding during embryogenesis.

206 * KDM5C was bound to the promoter of many genes dysregulated in both EpiLCs and brain datasets, including _D1P
207 * KDM5C was not bound to many of the brain-specific germline DEGs, such as XXX.
208 * While KDM5C binds to many germline DEGs in EpiLCs, including _Dazl_, many were also unbound. This included the
209 * All genes lacked binding in PNCs.
210 * Altogether, these data indicate that while some germline genes are misexpressed due to direct loss of KDM5C

211

212 Although KDM5C is generally thought to suppress transcription through erasure of histone 3 lysine 4 di- and trimethylation
213 (H3K4me2/3), recent studies in ESCs have suggested KDM5C's repression *Dazl* is independent of its catalytic activity¹⁸. It
214 is currently unclear if KDM5C's catalytic activity aids in the long-term repression of germline genes, such as enabling the
215 placement of DNA methylation.

216 • In congruence with previous work in the *Kdm5c*-KO hippocampus⁹, we observed ectopic H3K4me3 peaks in the
217 *Kdm5c*-KO amygdala at the transcription start site (TSS) of germline genes (Figure 4).
218 • We additionally observed a marked increase in H3K4me2 at germline gene promoters in *Kdm5c*-KO EpiLCs.
219 – This increase was greatest at germline genes directly bound by KDM5C (?)

220 Discussion

221 • The demarcation of the germ vs soma is a key feature of multicellularity

- 222 • Other H3K4me regulators, anything known about tissue-biased gene expression?
- 223 • tissue-biased gene expression:
- 224 – However unlike the gonadal-biased DEGs, many liver and muscle-biased DEGs have a known involvement in brain
225 function. For example, the liver-biased DEG is *Apolipoprotein C-I* (*Apoc1*), is important for lipoprotein metabolism
226 but has also been shown to influence learning and memory (Figure 1E).
- 227 • Otx2 is properly expressed in EpiLCs and prevents pgc identity <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6485399/>

310 **Figures and Tables**

311 —

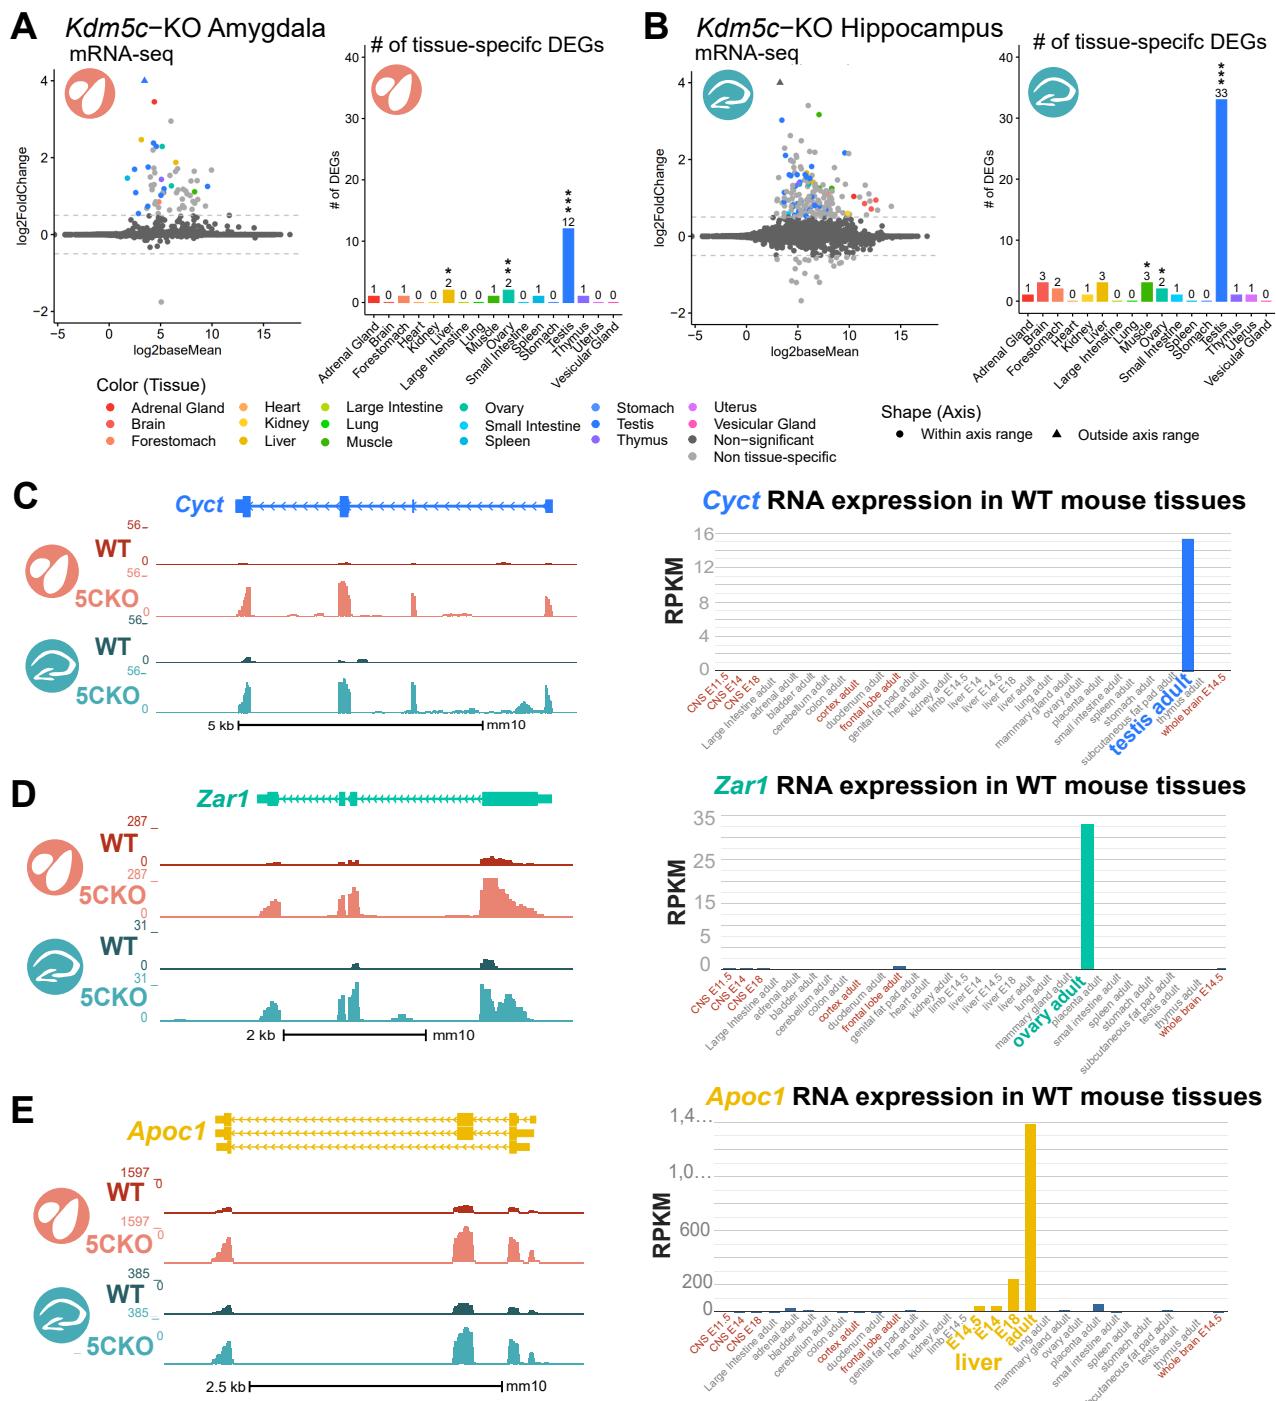

Figure 1: Tissue-enriched genes are misexpressed in the *Kdm5c*-KO brain. **A.** Expression of tissue-enriched genes in the male *Kdm5c*-KO amygdala. Left - MA plot of mRNA-seq. Right - Number of tissue-enriched differentially expressed genes (DEGs). * $p<0.05$, ** $p<0.01$, *** $p<0.001$, Fisher's exact test. **B.** Expression of tissue-enriched genes in the male *Kdm5c*-KO hippocampus. **C.** Left - Average bigwigs of an example aberrantly expressed testis-enriched DEG, *Cytochrome C, testis-specific* (*Cyct*) in the wild-type (WT) and *Kdm5c*-KO (5CKO) amygdala (red) and hippocampus (teal). Right - Expression of *Cyct* in wild-type tissues from NCBI Gene, with testis highlighted in blue and brain tissues highlighted in red. **D.** Left - Average bigwigs of an example ovary-enriched DEG, *Zygotic arrest 1* (*Zar1*). Right - Expression of *Zar1* in wild-type tissues from NCBI Gene, with ovary highlighted in teal and brain tissues highlighted in red. **E.** Left - Average bigwigs of an example liver-enriched DEG, *Apolipoprotein C-I* (*Apoc1*). Right - Expression of *Apoc1* in wild-type tissues from NCBI Gene, with liver highlighted in orange and brain tissues highlighted in red.

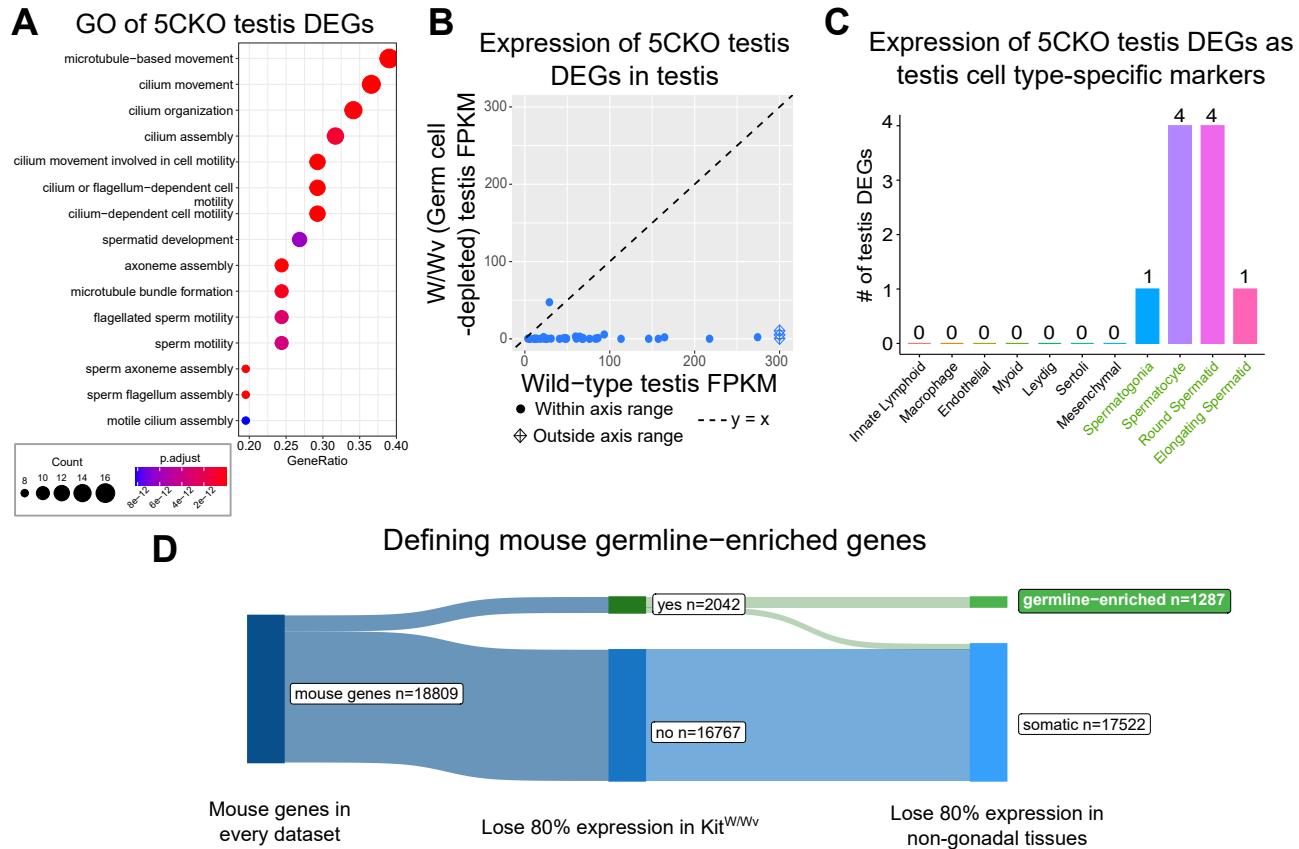

Figure 2: Aberrant transcription of germline genes in the *Kdm5c*-KO in the brain. **A.** enrichPlot gene ontology (GO) of *Kdm5c*-KO amygdala and hippocampus testis-enriched DEGs **B.** Expression of testis DEGs in wild-type (WT) testis versus germ cell-depleted (W/Wv) testis. Expression is in Fragments Per Kilobase of transcript per Million mapped reads (FPKM). **C.** Number of testis DEGs that were classified as cell-type specific markers in a single cell RNA-seq dataset of the testis (Green et al 2018). Germline cell types are highlighted in green, somatic cell types in black. **D.** Sankey diagram of mouse genes filtered for germline enrichment based on their expression in wild-type and germline-depleted mice and in adult mouse non-gonadal tissues (Li et al 2017).

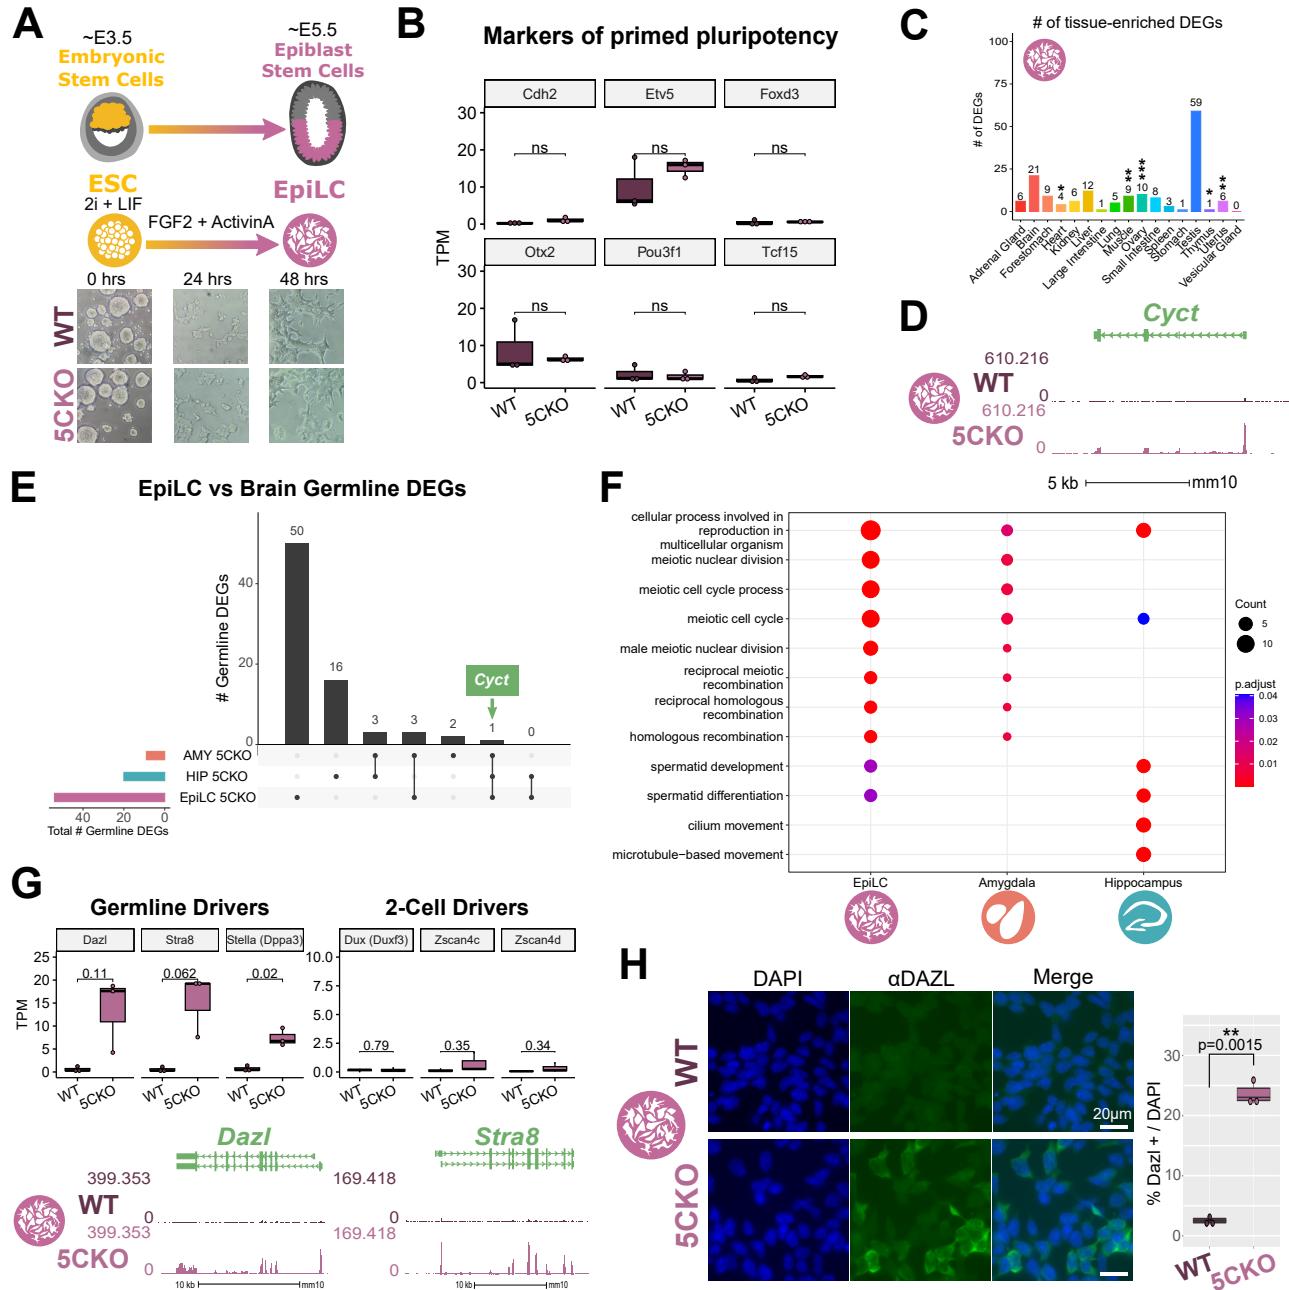

Figure 3: *Kdm5c*-KO epiblast-like cells express master regulators of germline identity

A. Top - Diagram of *in vivo* differentiation of embryonic stem cells (ESCs) of the inner cell mass into epiblast stem cells. Middle - *in vitro* differentiation of ESCs into epiblast-like cells (EpiLCs). Bottom - representative images of wild-type (WT) and *Kdm5c*-KO ESC to EpiLC differentiation. Brightfield images taken at 20X. **B.** No significant difference in primed pluripotency marker expression in wild-type versus *Kdm5c*-KO EpiLCs. Welch's t-test, expression in transcripts per million (TPM). **C.** Number of tissue-enriched differentially expressed genes (DEGs). * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, Fisher's exact test. **D.** Average bigwigs of an example germline gene, *Cyct*, that is dysregulated *Kdm5c*-KO EpiLCs. **E.** Upset plot displaying the overlap of germline DEGs expressed in *Kdm5c*-KO EpiLCs, amygdala (AMY), and hippocampus (HIP) RNA-seq datasets. **F.** enrichPlot comparing enriched gene ontologies for *Kdm5c*-KO EpiLCs, amygdala, and hippocampus germline DEGs. **G.** Top - Example germline identity DEGs unique to EpiLCs, p-values for Welch's t-test. Bottom - Average bigwigs of *Dazl* and *Stra8* expression in wild-type and *Kdm5c*-KO EpiLCs. **H.** Immunocytochemistry of DAZL in male wild-type (WT) and *Kdm5c*-KO (5CKO) EpiLCs. Percentage of DAZL-positive cells normalized to DAPI, p-value for Welch's t-test

312 **Figure outline:**

313 **Figure 1: Misexpression of tissue-specific genes in the *Kdm5c*-KO brain** * MA-plot and bar graphs of tissue-enriched
314 genes * Example testis-specific genes (NCBI and bigwigs) * An example ovary tissue-specific gene * An example muscle/liver
315 tissue-specific gene (NCBI and bigwigs)

316 **Figure 2: The male *Kdm5c*-KO brain expresses male and female germline-enriched genes** * Gene ontology of
317 testis DEGs in the amygdala and hippocampus - ontologies are germline ontologies * Expression of testis DEGs in germline-
318 depleted testis (this is adult testis data) * scRNASeq of testis - # of testis DEGs that are germline-specific markers * Although
319 far fewer, 5CKO brain also expresses ovary-enriched genes(NCBI and bigwigs of Zar1) * These ovary enriched genes are
320 also germline specific (NCBI/Li tissues are in adult ovary, so it would be best to show they're oocyte-specific in adult ovary.
321 But I don't think there's a published adult female W/Wv dataset. Could try looking at scRNASeq or just do TPM in embryonic
322 W/Wv data since oocytes are developed at this point? Or both?) * Defining what is/isn't a germline gene, and which are
323 male/female biased using embryonic W/Wv data

324 **Figure 3: *Kdm5c*-KO epiblast-like cells express master regulators of germline identity** * A) ESC to EpiLC differentia-
325 tion Left - Morphology is unchanged, * B) 5CKO EpiLCs express EpiLC differentiation genes similar to WT lvls * C) Male
326 EpiLCs express germline genes (example Cyct again) * Overlap between brain and EpiLC germline genes - show they're
327 mostly unique * GO of Brain and EpiLC germline genes (meiotic enriched) * Bigwigs or TPM of master regulators * Show
328 that while some are also 2-cell genes (Dazl), 2-cell specific genes aren't dysregulated (Zscan4). Important point because
329 published KDM5C dazl paper is saying KDM5C is a 2-cell regulator, but as far as I can tell only genes shared between
330 germline and 2-cell are dysregulated.

331 Staining of Dazl (+ Stra8 if I can get it to work)

332 **Figure 4: Loss of KDM5C's catalytic activity impairs DNAme placement and long-term silencing of germline
333 genes** * Increase in H3K4me3 in *Kdm5c*-KO amygdala at germline genes * Increase in H3K4me2 in EpiLCs at germline
334 genes * *Kdm5c* binding in EpiLCs vs PNCs to show that germline repression is happening in early embryo * Previous studies
335 only looked at ESCs, unknown if catalytic activity is required for long-term repression, especially since DNA methylation is
336 placed later). KDM5C RNA and protein ESC → EpiLC (increasing then decreasing) * RNA expression of germline genes with
337 catalytic dead rescue (Ilakkiya) * DNA methylation in WT and 5CKO EpiLCs (Ilakkiya)

338 **Figure 5: Ectopic, germline-like phenotypes in *Kdm5c*-KO ESCs/EpiLCs** * Sycp3 staining * DDX4 staining and
339 repression of retrotransposons * Cilia??
