

1 **Erosion of somatic tissue identity with loss of the X-linked**
2 **intellectual disability factor KDM5C**

3

4 Katherine M. Bonefas, Ilakkiya Venkatachalam, and Shigeki Iwase.

5 **Abstract**

6 Mutations in numerous chromatin-modifying enzymes cause neurodevelopmental disorders (NDDs).
7 Loss of repressive chromatin regulators can lead to the aberrant transcription of tissue-specific genes
8 outside of their intended context, however the mechanisms and consequences of their dysregulation are
9 largely unknown. Here, we explored this cellular identity crisis in NDDs by investigating lysine demethylase
10 5c (KDM5C), an eraser of histone 3 lysine 4 di and tri-methylation (H3K4me2/3), in tissue identity. We
11 found male *Kdm5c* knockout (-KO) mice, which recapitulate key behavioral phenotypes of Claes-Jensen
12 X-linked intellectual disability, aberrantly expresses many liver, muscle, ovary, and testis genes within the
13 amygdala and hippocampus. Gonad-enriched genes expressed in the *Kdm5c*-KO brain were typically
14 unique to germ cells, indicating an erosion of the soma-germline boundary. Germline genes are usually
15 decommissioned in somatic lineages in the post-implantation epiblast, yet *Kdm5c*-KO epiblast-like cells
16 (EpiLCs) aberrantly expressed key regulators of germline identity and meiosis, including *Dazl* and *Stra8*.
17 Germline gene suppression is sexually dimorphic, as female EpiLCs required a higher dose of KDM5C to
18 maintain germline gene suppression. Using a curated list of mouse germline-enriched genes, we found
19 KDM5C is selectively recruited to a subset of germline gene promoters that contain CpG islands (CGIs)
20 to facilitate DNA CpG methylation (CpGme) during ESC to EpiLC differentiation. However, late stage
21 spermatogenesis genes devoid of promoter CGIs can also become activated in *Kdm5c*-KO cells via ectopic
22 activation by RFX transcription factors. Thus, distinct suppressive mechanisms are recruited to different
23 germline gene classes and ectopic germline transcriptional programs can mirror germ cell development
24 within somatic tissues.

25 **Introduction**

26 A single genome holds the instructions to generate the myriad of cell types found within an organism.
27 This is, in part, accomplished by chromatin regulators that can either promote or impede lineage-specific

28 gene expression through DNA and histone modifications^{1–5}. Human genetic studies revealed mutations in
29 chromatin regulators are a major cause of neurodevelopmental disorders (NDDs)⁶ and many studies have
30 identified their importance for regulating brain-specific transcriptional programs. Loss of some chromatin
31 regulators can also result in the ectopic expression of tissue-specific genes outside of their target environment,
32 such as the misexpression of liver-specific genes within adult neurons⁷. However, the mechanisms underlying
33 ectopic gene expression and its impact upon neurodevelopment are poorly understood.

34 To elucidate the role of tissue identity in chromatin-linked NDDs, it is essential to first characterize the
35 nature of the dysregulated genes and the molecular mechanisms governing their de-repression. Here we
36 focus on lysine demethylase 5C (KDM5C, also known as SMCX or JARID1C), which erases histone 3 lysine
37 4 di- and trimethylation (H3K4me2/3), a permissive chromatin modification enriched at gene promoters⁸.
38 Pathogenic mutations in *KDM5C* cause Intellectual Developmental Disorder, X-linked, Syndromic, Claes-
39 Jensen Type (MRXSCJ, OMIM: 300534). MRXSCJ is more common and severe in males and its neurological
40 phenotypes include intellectual disability, seizures, aberrant aggression, and autistic behaviors^{9–11}. Male
41 *Kdm5c* knockout (-KO) mice recapitulate key MRXSCJ phenotypes, including hyperaggression, increased
42 seizure propensity, and learning impairments^{12,13}. RNA sequencing (RNA-seq) of the *Kdm5c*-KO hippocam-
43 pus surprisingly revealed ectopic expression of some germline genes within the brain¹³. However, it is unclear
44 if other tissue-specific genes are aberrantly transcribed with KDM5C loss, at what point in development
45 germline gene misexpression begins, and what mechanisms underlie their dysregulation.

46 Distinguishing between germ cells and somatic cells is a key feature of multicellularity¹⁴ that occurs
47 during early embryogenesis in many metazoans¹⁵. In mammals, chromatin regulators are crucial for
48 decommissioning germline genes during the transition from naïve to primed pluripotency. Initially, germline
49 gene promoters gain repressive histone H2A lysine 119 monoubiquitination (H2AK119ub1)¹⁶ and histone 3
50 lysine 9 trimethylation (H3K9me3)^{16,17} in embryonic stem cells (ESCs) and are then decorated with DNA
51 CpG methylation (CpGme) in the post-implantation embryo^{17–19}. The contribution of KDM5C to this process
52 remains unclear. Furthermore, studies on germline gene repression have primarily been conducted in males
53 and focused on marker genes important for germ cell development rather than germline genes as a whole,
54 given the lack of a curated list for germline-enriched genes. Therefore, it is unknown if the mechanism
55 of repression differs between sexes or for certain classes of germline genes, e.g. meiotic genes versus
56 spermatid differentiation genes.

57 To illuminate KDM5C's role in tissue identity, here we characterized the aberrant expression of tissue-
58 enriched genes within the *Kdm5c*-KO brain and epiblast-like stem cells (EpiLCs), an *in vitro* model of the
59 post-implantation embryo. We curated list of mouse germline-enriched genes, which enabled genome-wide
60 analysis of germline gene silencing mechanisms for the first time. Based on the data presented below, we
61 propose KDM5C plays a fundamental, sexually dimorphic role in the development of tissue identity during
62 early embryogenesis, including the establishment of the soma-germline boundary.

63 **Results**

64 **Tissue-enriched genes are aberrantly expressed in the *Kdm5c*-KO brain**

65 Previous RNA sequencing (RNA-seq) of the adult male *Kdm5c*-KO hippocampus revealed ectopic
66 expression of some germline genes unique to the testis¹³. It is currently unknown if the testis is the only
67 tissue type misexpressed in the *Kdm5c*-KO brain. We thus characterized the role of KDM5C in brain tissue
68 identity by systematically assessing the dysregulation of genes enriched in 17 mouse tissues²⁰. We analyzed
69 tissue-specific differentially expressed genes (DEGs) in our published mRNA-seq datasets²¹ of the adult
70 amygdala and hippocampus from wild-type and constitutive *Kdm5c*-KO male mice (DESeq2²², log2 fold
71 change > 0.5, q < 0.1).

72 We found a large proportion of significantly upregulated genes within the *Kdm5c*-KO brain are typically
73 enriched within non-brain tissues (Amygdala: 35%, Hippocampus: 24%) (Figure 1A-B). For both the
74 amygdala and hippocampus, the majority of tissue-enriched (DEGs) were testis genes (Figure 1A-C). Even
75 though the testis has the largest total number of tissue-biased genes (2,496 genes) compared to any other
76 tissue, testis-biased DEGs were significantly enriched for both brain regions (Amygdala p = 1.83e-05, Odds
77 Ratio = 5.13; Hippocampus p = 4.26e-11, Odds Ratio = 4.45, Fisher's Exact Test). One example of a
78 testis-enriched gene misexpressed in the *Kdm5c*-KO brain is *FK506 binding protein 6* (*Fkbp6*), a known
79 regulator of PIWI-interacting RNAs (piRNAs) and meiosis^{23,24} (Figure 1C).

80 Interestingly, we also observed significant enrichment of ovary-biased DEGs in both the amygdala and
81 hippocampus (Amygdala p = 0.00574, Odds Ratio = 18.7; Hippocampus p = 0.048, Odds Ratio = 5.88,
82 Fisher's Exact) (Figure 1A-B). Ovary-enriched DEGs included *Zygotic arrest 1* (*Zar1*), which sequesters
83 mRNAs in oocytes for meiotic maturation²⁵ (Figure 1D). Given that the *Kdm5c*-KO mice we analyzed are
84 male, these data demonstrate that the ectopic expression of gonad-enriched genes is independent of
85 organismal sex.

86 Although not consistent across brain regions, we also found significant enrichment of DEGs biased
87 towards two non-gonadal tissues - the liver (Amygdala p = 0.04, Odds Ratio = 6.58, Fisher's Exact Test) and
88 the muscle (Hippocampus p = 0.01, Odds Ratio = 6.95, Fisher's Exact Test) (Figure 1A-B). *Apolipoprotein*
89 *C-1* (*Apoc1*) a lipoprotein metabolism and transport gene, is among the liver-biased DEG derepressed in both
90 the hippocampus and amygdala²⁶ and its brain overexpression has been implicated in Alzheimer's disease²⁷
91 (Figure 1E).

92 For all *Kdm5c*-KO tissue-enriched DEGs, aberrantly expressed mRNAs are polyadenylated and spliced
93 into mature transcripts (Figure 1C-E). Of note, we observed little to no dysregulation of brain-enriched genes
94 (Amygdala p = 1, Odds Ratio = 1.22; Hippocampus p = 0.74, Odds Ratio = 1.22, Fisher's Exact), despite the
95 fact these are brain samples and the brain has the second highest total number of tissue-enriched genes
96 (708 genes). Altogether, these results suggest the aberrant expression of tissue-enriched genes within the
97 brain is a major effect of KDM5C loss.

98 **Germline genes are misexpressed in the *Kdm5c*-KO brain**

99 *Kdm5c*-KO brain expresses testicular germline genes¹³, however the testis also contains somatic cells that
100 support hormone production and germline functions. To determine if *Kdm5c*-KO results in ectopic expression
101 of somatic testicular genes, we first evaluated the known functions of testicular DEGs through gene ontology.
102 We found *Kdm5c*-KO testis-enriched DEGs had high enrichment of germline-relevant ontologies, including
103 spermatid development (GO: 0007286, p.adjust = 6.2e-12) and sperm axoneme assembly (GO: 0007288,
104 p.adjust = 2.45e-14) (Figure 2A).

105 We then evaluated testicular DEG expression in wild-type testes versus testes with germ cell depletion²⁸,
106 which was accomplished by heterozygous *W* and *Wv* mutations in the enzymatic domain of *c-Kit* (*Kit*^{W/Wv})²⁹.
107 Almost all *Kdm5c*-KO testis-enriched DEGs lost expression with germ cell depletion (Figure 2B). We then
108 assessed testis-enriched DEG expression in a published single cell RNA-seq dataset that identified cell
109 type-specific markers within the testis³⁰. Some *Kdm5c*-KO testis-enriched DEGs were classified as specific
110 markers for different germ cell developmental stages (e.g. spermatogonia, spermatocytes, round spermatids,
111 and elongating spermatids), yet none marked somatic cells (Figure 2C). Together, these data demonstrate
112 that the *Kdm5c*-KO brain aberrantly expresses germline genes, but not somatic testicular genes, reflecting
113 an erosion of the soma-germline boundary.

114 As of yet, research on germline gene silencing mechanisms has focused on a handful of key genes
115 rather than assessing germline gene suppression genome-wide due to the lack of a comprehensive gene list.
116 We therefore generated a list of mouse germline-enriched genes using RNA-seq datasets of *Kit*^{W/Wv} mice
117 that included males and females at embryonic day 12, 14, and 16³¹ and adult male testes²⁸. We defined
118 genes as germline-enriched if their expression met the following criteria: 1) their expression is greater than
119 1 FPKM in wild-type gonads 2) their expression in any non-gonadal tissue of adult wild type mice²⁰ does
120 not exceed 20% of their maximum expression in the wild-type germline, and 3) their expression in the germ
121 cell-depleted gonads, for any sex or time point, does not exceed 20% of their maximum expression in the
122 wild-type germline. These criteria yielded 1,288 germline-enriched genes (Figure 2D), which was hereafter
123 used as a resource to globally characterize germline gene misexpression with *Kdm5c* loss (Supplementary
124 table 1).

125 ***Kdm5c*-KO epiblast-like cells aberrantly express key regulators of germline identity**

126 Germ cells are typically distinguished from somatic cells soon after the embryo implants into the uterine
127 wall^{32,33}, when they are silenced in epiblast stem cells that will differentiate into the ectoderm, mesoderm,
128 and endoderm to form the somatic tissues³⁴. This developmental time point can be modeled *in vitro* through
129 differentiation of naïve embryonic stem cells (nESCs) into epiblast-like stem cells (EpiLCs) (Figure 3A)^{35,36}.
130 While some germline-enriched genes are also expressed in nESCs and in the 2-cell stage³⁷⁻³⁹, they are
131 silenced as they differentiate into EpiLCs^{17,40}. Therefore, we tested if KDM5C was necessary for the initial

132 silencing germline genes in somatic lineages by evaluating the impact of *Kdm5c* loss in male EpiLCs.
133 *Kdm5c*-KO cell morpholgy during ESC to EpiLC differentiation appeared normal (Figure 3B) and EpiLCs
134 properly expressed markers of primed pluripotency, such as *Dnmt3b*, *Fgf5*, *Pou3f1*, and *Otx2* (Figure 3C).
135 We then identified tissue-enriched DEGs in our previously published RNA-seq dataset of wild-type and
136 *Kdm5c*-KO EpiLCs⁴¹ (DESeq2, log2 fold change > 0.5, q < 0.1). Similar to the *Kdm5c*-KO brain, we observed
137 general dysregulation of tissue-enriched genes, with the largest number of genes belonging to the brain and
138 testis, although they were not significantly enriched (Figure 3D). Using our list of mouse germline-enriched
139 genes assembled above, we found 54 germline genes were misexpressed in male *Kdm5c*-KO EpiLCs.

140 We then compared EpiLC germline DEGs to those expressed in the *Kdm5c*-KO brain to determine if
141 germline genes are constitutively dysregulated or change over the course of development. The majority
142 of germline DEGs were unique to either EpiLCs or the brain, with only *Cyct* shared across all tissue/cell
143 types (Figure 3E-F). EpiLCs had particularly high enrichment of meiosis-related gene ontologies (Figure
144 3G), such as meiotic cell cycle process (GO:1903046, p.adjust = 1.59e-08) and meiotic nuclear division
145 (GO:0140013, p.adjust = 9.76e-09). While there was modest enrichment of meiotic gene ontologies in both
146 brain regions, the *Kdm5c*-KO hippocampus primarily expressed late-stage spermatogenesis genes involved
147 in sperm axoneme assembly (GO:0007288, p.adjust = 0.00621) and sperm motility (GO:0097722, p.adjust =
148 0.00612).

149 Notably, DEGs unique to *Kdm5c*-KO EpiLCs included key drivers of germline identity, such as *Stimulated*
150 *by retinoic acid 8* (*Stra8*: log2 fold change = 3.7, q = 2.05e-26) and *Deleted in azoospermia like* (*Dazl*: log2
151 fold change = 3.16, q = 4.08e-06) (Figure 3H). These genes are typically expressed when primordial germ
152 cells (PGCs) are committed to the germline fate, but are also expressed later in life to trigger meiotic gene
153 expression programs⁴²⁻⁴⁴. Of note, some germline genes, including *Dazl*, are also expressed in the two-cell
154 embryo^{38,45}. However, we did not see derepression of two-cell stage-specific genes, like *Duxf3* (*Dux*) (log2
155 fold change = -0.282, q = 0.337) and *Zscan4d* (log2 fold change = 0.25, q = 0.381) (Figure 3H), indicating
156 *Kdm5c*-KO EpiLCs do not revert back to a 2-cell-like state. Altogether, *Kdm5c*-KO EpiLCs expressing key
157 drivers of germline identity and meiosis while the brain primarily expresses spermiogenesis genes indicate
158 germline gene misexpression parallels germline development during proper *Kdm5c*-KO differentiation.

159 **Female epiblast-like cells have increased sensitivity to germline gene misexpression 160 with *Kdm5c* loss**

161 It is currently unknown if the misexpression of germline genes is influenced by sex, as previous studies
162 on germline gene repressors have focused on males^{16-18,46,47}. Sex is particularly pertinent in the case
163 of KDM5C because it partially escapes X chromosome inactivation (XCI), resulting in a higher dosage in
164 females⁴⁸⁻⁵¹. We therefore explored the impact of chromosomal sex upon germline gene suppression by
165 comparing their dysregulation in male *Kdm5c* hemizygous knockout (XY *Kdm5c*-KO), female homozygous

166 knockout (XX *Kdm5c*-KO), and female heterozygous knockout (XX *Kdm5c*-HET) EpiLCs.⁴¹.
167 Homozygous and heterozygous *Kdm5c* knockout females expressed over double the number of germline-
168 enriched genes than hemizygous males (Figure 4A). While the majority of germline DEGs in *Kdm5c*-KO
169 males were also dysregulated in females (74%), many were male-specific and female-specific, such as
170 *Tktl2* and *Esx1* (Figure 4B). We then compared the known functions of germline genes dysregulated only in
171 females (XX only - dysregulated in XX *Kdm5c*-KO, XX *Kdm5c*-HET, or both), only in males (XY only), or in
172 all samples (shared) (Figure 4C). Female-specific germline DEGs were enriched for meiotic (GO:0051321
173 meiotic cell cycle) and flagellar (GO:0003341 cilium movement) functions, while male-specific DEGs had
174 roles in mitochondrial and cell signaling (GO:0070585 protein localization to mitochondrion). Germline
175 transcripts expressed in both sexes were enriched for meiotic (GO:0140013 meiotic nuclear division) and
176 egg-specific functions (GO:0007292 female gamete generation).

177 The majority of germline genes expressed in both sexes had a greater log2 fold change in females
178 compared to males (Figure 4D-F). This increased degree of dysregulation in females, along with the
179 increased total number of germline genes, indicates females are more sensitive to losing KDM5C-mediated
180 germline gene suppression. Female sensitivity could be due to impaired XCI in *Kdm5c* mutants⁴¹, as many
181 spermatogenesis genes lie on the X chromosome^{52,53}. However, female germline DEGs were not biased
182 towards the X chromosome and had a similar overall proportion of X chromosome DEGs compared to
183 males (XY *Kdm5c*-KO - 10.29%, XX *Kdm5c*-HET - 7.43%, XX *Kdm5c*-KO - 10.59%) (Figure 4G). The
184 majority of germline DEGs instead lie on autosomes for both male and female *Kdm5c* mutants (Figure 4G).
185 Thus, while female EpiLCs are more prone to germline gene misexpression with KDM5C loss, it is likely
186 independent of XCI defects.

187 **Germline gene misexpression in *Kdm5c* mutants is independent of germ cell sex**

188 Although many germline genes have shared functions in the male and female germline, some have
189 unique or sex-biased expression. Therefore, we wondered if *Kdm5c* mutant males would primarily express
190 sperm genes while mutant females primarily expressed egg genes. To comprehensively assess whether
191 germline gene sex corresponds with *Kdm5c* mutant sex, we first filtered our list of germline-enriched genes
192 for egg and sperm-biased genes (Figure 4H). We defined germ cell sex-biased genes as those whose
193 expression in the opposite sex, at any time point, is no greater than 20% of the gene's maximum expression
194 in a given sex. This yielded 67 egg-biased, 1,024 sperm-biased, and 197 unbiased germline-enriched genes.
195 We found egg, sperm, and unbiased germline genes were dysregulated in all *Kdm5c* mutants at similar
196 proportions (Figure 4I-J). Furthermore, germline genes dysregulated exclusively in either male or female
197 mutants were also not biased towards their corresponding germ cell sex (Figure 4I). Altogether, these results
198 demonstrate sex differences in germline gene dysregulation is not due to sex-specific activation of sperm or
199 egg transcriptional programs.

200 **KDM5C binds to a subset of germline gene promoters during early embryogenesis**

201 KDM5C binds to the promoters of several germline genes in embryonic stem cells (ESCs) but its binding
202 is absent in neurons¹³. However, the lack of a comprehensive list of germline-enriched genes prohibited
203 genome-wide characterization of KDM5C binding at germline gene promoters. Thus, it is unclear if KDM5C
204 is enriched at germline gene promoters, what types of germline genes KDM5C regulates, and if its binding is
205 maintained at any germline genes in neurons.

206 To address these questions, we analyzed KDM5C chromatin immunoprecipitation followed by DNA
207 sequencing (ChIP-seq) datasets in EpiLCs⁴¹ and primary forebrain neuron cultures (PNCs)¹². EpiLCs had a
208 higher total number of high-confidence KDM5C peaks than PNCs (EpiLCs: 5,808, PNCs: 1,276, MACS2 q <
209 0.1 and fold enrichment > 1). KDM5C was primarily localized to gene promoters in both cell types (EpiLCs:
210 4,190, PNCs: 745 ± 500bp from the TSS), although PNCs showed increased localization to non-promoter
211 regions (Figure 5A).

212 The majority of promoters bound by KDM5C in PNCs were also bound in EpiLCs (513 shared promoters),
213 however a large portion of gene promoters were only bound by KDM5C in EpiLCs (3,677 EpiLC only
214 promoters) (Figure 5B). Genes bound by KDM5C in both PNCs and EpiLCs were enriched for functions
215 involving nucleic acid turnover, such as deoxyribonucleotide metabolic process (GO:0009262, p.adjust =
216 8.28e-05) (Figure 5C). Germline-specific ontologies were only enriched in KDM5C-bound promoters unique
217 to EpiLCs, such as meiotic nuclear division (GO: 0007127 p.adjust = 6.77e-16) and meiotic cell cycle process
218 (GO:1903046, p.adjust = 5.05e-16) (Figure 5C). There were no ontologies significantly enriched for genes
219 bound by KDM5C only in PNCs. Using our mouse germline gene list, we observed evident KDM5C signal
220 around the TSS of many germline genes in EpiLCs, but not in PNCs (Figure 5D). Based on our ChIP-seq
221 peak cut-off criteria, KDM5C was highly enriched at 211 germline gene promoters in EpiLCs (0.164% of all
222 germline genes) (Figure 5E). Of note, KDM5C was only bound to about one third of *Kdm5c*-KO RNA-seq
223 DEG promoters (EpiLC only DEGs: 36%, Brain only DEGs: 33.3%) (Supplementary figure 1A-C). However,
224 KDM5C was bound to the promoter at 3 out of the 4 genes dysregulated in both the brain and EpiLCs.
225 Representative examples of KDM5C-bound and unbound germline DEGs are *Dazl* and *Stra8*, respectively
226 (Figure 5F). Together, these results demonstrate KDM5C is recruited to a subset of germline genes in EpiLCs,
227 including meiotic genes, but does not directly regulate germline genes in neurons. Furthermore, the majority
228 of germline mRNAs expressed in *Kdm5c*-KO cells are dysregulated independent of direct KDM5C binding to
229 their promoters.

230 Many germline-specific genes are suppressed by the polycomb repressive complex 1.6 (PRC1.6), which
231 contains transcription factor heterodimers E2F6/DP1 and MGA/MAX that respectively bind E2F and E-box
232 motifs⁵⁶. PRC1.6 members have been proposed to recruit KDM5C to germline gene promoters, given
233 their association in HeLa cells and ESCs^{45,57} and that KDM5C itself does not contain sequence-specific
234 binding domains⁸. To elucidate how KDM5C is recruited to germline genes, we used HOMER⁵⁸ to identify
235 transcription factor motifs enriched at KDM5C-bound or unbound germline gene promoters (TSS ± 500

236 bp, q-value < 0.1). MAX and E2F6 binding sites were significantly enriched at germline genes bound by
237 KDM5C in EpiLCs, but not at germline genes unbound by KDM5C (MAX q-value: 0.0068, E2F6 q-value:
238 0.0673, E2F q-value: 0.0917) (Figure 5G). One third of KDM5C-bound promoters contained the consensus
239 sequence for either E2F6 (E2F, 5'-TCCCGC-3'), MGA (E-box, 5'-CACGTG-3'), or both, but only 17% of
240 KDM5C-unbound genes contained these motifs (Figure 5H). KDM5C-unbound germline genes were instead
241 enriched for multiple RFX transcription factor binding sites (RFX q-value < 0.0001, RFX2 q-value < 0.0001,
242 RFX5 q-value < 0.0001) (Figure 5I, Supplementary figure 1D). RFX transcription factors bind X-box motifs⁵⁹
243 to promote ciliogenesis^{60,61} and among them is RFX2, a central regulator of post-meiotic spermatogenesis^{62,63}.
244 Interestingly, RFX2 mRNA is derepressed in *Kdm5c*-KO EpiLCs (Figure 5J), however it is also not a direct
245 target of KDM5C (Supplementary figure 1E). Thus, RFX2 is a candidate transcription factor for driving the
246 ectopic expression of KDM5C-unbound germline genes in *Kdm5c*-KO cells.

247 **KDM5C is recruited to CpG islands within germline gene promoters to facilitate de
248 novo DNA methylation**

249 In the early embryo, germline gene promoters are initially decorated with repressive histone modifications
250 and are then silenced long-term via DNA CpG methylation (CpGme)^{16,17,40,64}. Our results above indicate
251 KDM5C also acts at germline gene promoters during this time period. However, how KDM5C interacts with
252 other germline gene silencing mechanisms is currently unclear. KDM5C is generally thought to suppress
253 transcription through erasure of histone 3 lysine 4 di- and trimethylation (H3K4me2/3)⁸, yet KDM5C's
254 catalytic activity was recently shown to be dispensable for suppressing *Dazl* in undifferentiated ESCs⁴⁵. Since
255 H3K4me3 impedes *de novo* CpGme placement^{65,66}, KDM5C's catalytic activity may instead be required
256 in the post-implantation embryo for long-term silencing of germline genes. In support of this, CpGme is
257 markedly reduced at two germline gene promoters in the *Kdm5c*-KO adult hippocampus¹³.

258 Based on the above observations, we hypothesized KDM5C erases H3K4me3 to promote the initial
259 placement of CpGme at germline gene promoters in EpiLCs. To test this hypothesis, we first characterized
260 KDM5C's substrates (H3K4me2/3) at germline gene promoters in our published ChIP-seq datasets of male
261 wild-type and *Kdm5c*-KO amygdala²¹ and EpiLCs⁴¹. In congruence with the *Kdm5c*-KO hippocampus¹³,
262 we observed aberrant accumulation of H3K4me3 around the TSS of germline genes in the *Kdm5c*-KO
263 amygdala (Figure 6A). There was also a marked increase in H3K4me2 around the TSS of germline genes
264 in *Kdm5c*-KO EpiLCs (Figure 6B). To elucidate KDM5C's embryonic role, we then characterized KDM5C's
265 mRNA and protein expression during male ESC to EpiLC differentiation (Figure 6C). While *Kdm5c* mRNA
266 steadily decreased from 0 to 48 hours of differentiation (Figure 6D), KDM5C protein initially increased from
267 0 to 24 hours but then decreased to near knockout levels by 48 hours (Figure 6E). Together, these data
268 suggest KDM5C acts during the transition between ESCs and EpiLCs to remove H3K4me at germline gene
269 promoters.

270 Germline genes accumulate CpG methylation (CpGme) at CpG islands (CGIs) during the transition from
271 naïve to primed pluripotency^{19,40,67}, reaching peak methylation levels when differentiated into EpiLCs for
272 96 hours (extended EpiLCs, exEpiLCs)¹⁷. We first identified how many germline genes contained CGIs
273 using the UCSC genome browser⁶⁸ and found out of 1,288 germline-enriched genes, only 356 (27.64%)
274 had promoter CGIs (TSS ± 500 bp) (Figure 6F). CGI-containing germline genes were enriched for meiotic
275 gene ontologies, including meiotic nuclear division (GO:XXXX, p.adj) and meiosis I (GO:XXXX, p.adj) when
276 compared to CGI-free genes (Figure 6G). Although a minor portion of germline gene promoters contained
277 CGIs, CGIs strongly determined KDM5C's recruitment to germline genes (FISHER'S XXXX), with 79.15% of
278 KDM5C-bound germline genes containing CGIs (Figure 6G).

279 To assess how KDM5C loss impacts initial CpGme placement at germline gene promoters, we performed
280 whole genome bisulfite sequencing (WGBS) in male wild-type and *Kdm5c*-KO ESCs and 96 hour extended
281 EpiLCs (exEpiLCs) (Figure 6H). We first identified which germline gene promoters significantly gained
282 CpGme in wild-type cells during nESC to exEpiLCs differentiation (methylKit⁶⁹, q < 0.01, |methylation
283 difference| >= 25%, TSS ± 500 bp). In wild-type cells, the majority of germline genes gained substantial
284 CpGme at their promoter during differentiation (60.08%), regardless if their promoter contained a CGI (Figure
285 6I).

286 We then identified germline gene promoters differentially methylated in wild-type versus *Kdm5c*-KO
287 exEpiLCs (methylKit, q < 0.01, |methylation difference| > 25%, TSS ± 500 bp) and found 28 germline
288 promoters were significantly hypomethylated with *Kdm5c* loss (Figure 6J). Approximately half of germline
289 promoters hypomethylated in *Kdm5c*-KO exEpiLCs are direct targets of KDM5C in EpiLCs (13 out of 28
290 hypomethylated DMRs). Promoters that showed the most robust loss of CpGme (low q-values) harbored
291 CGIs (Figure 6J). We then evaluated promoter CpGme at germline genes ectopically transcribed in either
292 *Kdm5c*-KO EpiLCs or within the brain and found promoter CpGme was substantially reduced in about
293 half of germline DEGs (Figure 6K). Significantly hypomethylated promoters included genes consistently
294 dysregulated across multiple *Kdm5c*-KO RNA-seq datasets[], such as *Naa11* and *D1PAs1* (methylation
295 difference = -60.03%, q-value = 3.26e-153) (Figure 6L). Surprisingly, we observed only a modest reduction in
296 CpGme at *Dazl*'s promoter (methylation difference = -6.525%, q-value = 0.0159) (Figure 6M). Altogether,
297 these results demonstrate KDM5C is recruited to germline gene CGIs to promote CpGme at germline gene
298 promoters during early embryogenesis, however some loci can compensate for KDM5C loss through other
299 silencing mechanisms, even when retaining H3K4me.

300 Discussion

301 In the above study, we demonstrate KDM5C's pivotal role in the development of tissue identity. We
302 first characterized tissue-enriched genes expressed within the *Kdm5c*-KO brain and identified substantial
303 dysregulation of testis, liver, muscle, and ovary-enriched genes. Testis genes significantly enriched within

304 the *Kdm5c*-KO amygdala and hippocampus are specific to the germline and not expressed within somatic
305 cells. *Kdm5c*-KO epiblast-like cells (EpiLCs) aberrantly express key drivers of germline identity and meiosis,
306 including *Dazl* and *Stra8*, while the adult brain primarily expresses genes important for late spermatogenesis.
307 We demonstrated that although *Kdm5c* mutant sex did not influence whether sperm or egg-specific genes
308 were misexpressed, female EpiLCs are more sensitive to germline gene de-repression. Germline genes
309 can become aberrantly expressed in *Kdm5c*-KO cells via an indirect mechanism, such as activation via
310 ectopic RFX transcription factors. Finally, we found KDM5C is dynamically regulated during ESC to EpiLC
311 differentiation to promote long-term germline gene silencing through DNA methylation at CpG islands.
312 Therefore, we propose KDM5C plays a fundamental role in the development of tissue identity during
313 early embryogenesis, including the establishment of the soma-germline boundary. By systematically
314 characterizing KDM5C's role in germline gene repression, including its interaction with known silencing
315 mechanisms, we unveiled repressive mechanisms governing distinct classes of germline gene in somatic
316 lineages. Furthermore, these data provide molecular footholds which can be exploited to test the overarching
317 contribution of ectopic germline gene expression upon neurodevelopment.

318 Although eggs and sperm employ the same transcriptional programs for shared functions, e.g. PGC
319 formation, meiosis, and genome defense, some germline genes are sex specific. We found *Kdm5c* mutant
320 males and females expressed both sperm and egg-biased genes, indicating the mechanism of derepression
321 is independent of a given germline gene's sex. However, organismal sex did greatly influence the degree of
322 germline gene dysregulation, as female *Kdm5c*-KO EpiLCs had over double the number of germline-enriched
323 DEGs compared to males. The lack of X-linked gene enrichment in females suggests that this greater
324 sensitivity to germline gene misexpress is not due to XCI defects previously reported in *Kdm5c*-KO females⁴¹.
325 Sex differences in germline gene suppression may be a consequence of females having a higher dose of
326 KDM5C than males, due to its escape from XCI^{48–51}. Intriguingly, females with heterozygous loss of *Kdm5c*
327 also had over double the number of germline DEGs than hemizygous knockout males, even though their
328 level of KDM5C should be roughly equivalent to that of wild-type males. Altogether, these results suggests
329 germline gene silencing mechanims differ between males and females, which warrants further study to
330 identify the biological implications and underlying mechanisms.

331 It is important to note that while we highlighted KDM5C's regulation of germline genes, some germline-
332 enriched genes are also expressed at the 2-cell stage and in naïve ESCs for their role in pluripotency and
333 self-renewal^{39,45,70,71}. For example, while *Dazl* is primarily known for regulating the translation of germline-
334 specific mRNAs, it is also expressed at the 2-cell stage⁷¹, in naïve ESCs³⁷, and in the inner cell mass³⁷.
335 KDM5C was thought to promote the 2-cell-to-ESC transition, given *Dazl* and *Zscan4c* are de-repressed
336 in *Kdm5c*-KO ESCs⁴⁵. Although expressed in naïve ESCs, “self-renewal” germline genes like *Dazl* are
337 silenced during ESC differentiation into epiblast stem cells/EpiLCs^{17,40}. We found that while *Kdm5c*-KO
338 EpiLCs also express *Dazl*, they did not express 2-cell-specific genes. These data suggest the 2-cell-like
339 state observed in *Kdm5c*-KO ESCs likely reflects KDM5C's primary role in germline gene repression.

340 Germline gene misexpression in *Kdm5c*-KO EpiLCs may indicate they are differentiating into primordial germ
341 cell-like cells (PGCLCs), rather than de-differentiating into 2-cell-like cells^{32,33,35}. Yet, *Kdm5c*-KO EpiLCs
342 had normal cellular morphology and properly expressed markers for primed pluripotency, including *Otx2*
343 which is known to repress EpiLC differentiation into PGCs/PGCLCs⁷². In addition to unimpaired EpiLC
344 differentiation, *Kdm5c*-KO gross brain morphology is overall normal¹² and hardly any brain-specific genes
345 were significantly dysregulated. Thus, ectopic germline gene expression occurs in parallel with proper
346 *Kdm5c*-KO differentiation and somatic development.

347 While promoter CGIs are typically resistant to CpGme⁷³, CGIs at germline promoters are highly methylated
348 in somatic cells⁷⁴. In EpiLCs, loss of KDM5C binding at a subset of germline gene promoters,
349 e.g. *D1Pas1* and *Naa11*, strongly impaired CGI methylation, which resulted in their long-lasting de-repression
350 into adulthood. Removal of H3K4me2/3 at CGIs is a plausible mechanism for KDM5C-mediated germline
351 gene suppression^{13,75}, given H3K4me2/3 primarily do not colocalize with CpGme⁷⁴ and can oppose DNMT3
352 activity^{65,66}. However, emerging work indicates many histone-modifying enzymes have non-catalytic functions
353 that influence gene expression, sometimes even more potently than their catalytic roles^{76,77}. Indeed,
354 KDM5C's catalytic activity was recently found to be dispensable for repressing *Dazl* in ESCs⁴⁵. In our study,
355 *Dazl*'s promoter still gained CpGme in *Kdm5c*-KO exEpiLCs, even with elevated H3K4me2. *Dazl* and a few
356 other germline gene CGIs use multiple repressive mechanisms to facilitate CpGme^{16,17,46,47}. Together, this
357 suggests alternative silencing mechanisms are sufficient to recruit DNMT3s to some germline CGIs, while
358 others may require KDM5C-mediated H3K4me removal to overcome promoter CGI escape from CpGme.
359 Furthermore, these results indicate the requirement for catalytic activity for the same class of genes can
360 change depending upon the locus and developmental stage.

361 By generating a comprehensive list of mouse germline-enriched genes, we were able to reveal distinct
362 repressive mechanisms governing early versus late-stage germline developmental programs. In EpiLCs,
363 KDM5C was highly enriched at germline promoters containing CGIs, many of which had roles in early
364 germ cell formation and meiosis. However, over 70% of germline-enriched gene promoters lacked CGIs,
365 including the many KDM5C-unbound germline genes that were de-repressed in *Kdm5c*-KO cells. CGI-free,
366 KDM5C-unbound germline genes were primarily late-stage spermatogenesis genes and significantly
367 enriched for RFX2 binding sites, a central regulator of spermiogenesis^{62,63}. These data suggest that once
368 activated during early embryogenesis, drivers of germline identity like *Rfx2* and *Dazl* turn on downstream
369 germline programs that can loosely mimic germ cell development, ultimately culminating in the expression of
370 spermiogenesis genes in the adult *Kdm5c*-KO brain. Therefore, we propose KDM5C is recruited to germline
371 genes that shape germ cell formation via their promoter CGIs to act as break against runaway activation of
372 germline-specific programs. Therefore, we propose KDM5C is recruited via promoter CGIs to genes that
373 shape germ cell formation and acts as break against runaway activation of germline-specific programs.

374 The above work provides the mechanistic foundation for KDM5C-mediated repression of tissue and
375 germline-specific genes. However, the contribution of these ectopic, tissue-specific genes towards *Kdm5c*-

376 KO neurological impairments is still unknown. In addition to germline genes, we also identified significant
377 enrichment of muscle, liver, and even ovary-biased transcripts within the male *Kdm5c*-KO brain. Intriguingly,
378 select liver and muscle-biased DEGs do have known roles within the brain, such as the liver-enriched lipid
379 metabolism gene *Apolipoprotein C-I* (*Apoc1*)²⁶. *APOC1* dysregulation is implicated in Alzheimer's disease in
380 humans²⁷ and overexpression of *Apoc1* in the mouse brain can impair learning and memory⁷⁸. KDM5C may
381 therefore be crucial for neurodevelopment by fine-tuning the expression of tissue-enriched, dosage-sensitive
382 genes like *Apoc1*. Given germline genes have no known functions within the brain, their impact upon
383 neurodevelopment is currently unknown. Ectopic testicular germline transcripts have been observed in a
384 variety of cancers^{79,80}, including brain tumors in *Drosophila* and mammals^{81,82}, indicating their dysregulation
385 may promote genome instability and cellular de-differentiation. Intriguingly, some models for other chromatin-
386 linked neurodevelopmental disorders also display impaired soma-germline demarcation^{7,83–86}. Like KDM5C,
387 the chromatin regulators underlying these conditions - DNA methyltransferase 3b (DNMT3B), H3K9me1/2
388 methyltransferases G9A/GLP, methyl-CpG -binding protein 2 (MECP2) - primarily silence gene expression.
389 Thus, KDM5C is among a growing cohort of chromatin-linked neurodevelopmental disorders with similar
390 erosion of the germline versus soma boundary. Further research is required to determine the impact of these
391 germline genes and the extent to which this phenomenon occurs in humans.

392 Materials and Methods

393 Classifying tissue-enriched and germline-enriched genes

394 Tissue-enriched differentially expressed genes (DEGs) were determined by their classification in a previ-
395 ously published dataset from 17 male and female mouse tissues²⁰. This study defined tissue expression as
396 greater than 1 Fragments Per Kilobase of transcript per Million mapped read (FPKM) and tissue enrichment
397 as at least 4-fold higher expression than any other tissue.

398 We curated a list of germline-enriched genes using an RNA-seq dataset from wild-type and germline-
399 depleted (*Kit*^{W/Wv}) male and female mouse embryos from embryonic day 12, 14, and 16³¹, as well as adult
400 male testes²⁸. Germline-enriched genes met the following criteria: 1) their expression is greater than 1
401 FPKM in wild-type germline 2) their expression in any wild-type somatic tissues²⁰ does not exceed 20%
402 of maximum expression in wild-type germline, and 3) their expression in the germ cell-depleted (*Kit*^{W/Wv})
403 germline, for any sex or time point, does not exceed 20% of maximum expression in wild-type germline.

404 Cell culture

405 We utilized our previously established cultures of male wild-type and *Kdm5c* knockout (-KO) embryonic
406 stem cells⁴¹. Sex was confirmed by genotyping *Uba1/Uba1y* on the X and Y chromosomes with the following
407 primers: 5'-TGGATGGTGTGCCATTG-3', 5'-CACCTGCACGTTGCCCTT-3'. Deletion of *Kdm5c* was

408 confirmed through the primers 5'-ATGCCCATATTAAGAGTCCCTG-3', 5'-TCTGCCTTGATGGGACTGTT-3',
409 and 5'-GGTTCTAACACTCACATAGTG-3'.

410 Embryonic stem cells (ESCs) and epiblast-like cells were cultured using previously established
411 methods³⁶. Briefly, ESCs were initially cultured in primed ESC (pESC) media consisting of KnockOut
412 DMEM (Gibco#10829–018), fetal bovine serum (Gibco#A5209501), KnockOut serum replacement
413 (Invitrogen#10828–028), Glutamax (Gibco#35050-061), Anti-Anti (Gibco#15240-062), MEM Non-essential
414 amino acids (Gibco#11140-050), and beta-mercaptoethanol (Sigma#M7522). They were then transitioned
415 into ground-state, “naïve” ESCs (nESCs) by culturing for four passages in N2B27 media containing
416 DMEM/F12 (Gibco#11330–032), Neurobasal media (Gibco#21103–049), Gluamax, Anti-Anti, N2 sup-
417 plement (Invitrogen#17502048), and B27 supplement without vitamin A (Invitrogen#12587-010), and
418 beta-mercaptoethanol. Both pESC and nESC media were supplemented with 3 μ M GSK3 inhibitor
419 CHIR99021 (Sigma #SML1046-5MG), 1 μ M MEK inhibitor PD0325901 (Sigma #PZ0162-5MG), and 1,000
420 units/mL leukemia inhibitory factor (LIF, Millipore#ESG1107).

421 nESCs were differentiated into epiblast-like cells (EpiLCs, 48 hours) and extendend EpiLCs (exEpiLCs,
422 96 hours) by culturing in N2B27 media containing DMEM/F12, Neurobasal media, Gluamax, Anti-Anti,
423 N2 supplement, B27 supplement (Invitrogen#17504044), beta-mercaptoethanol, fibroblast growth factor 2
424 (FGF2, R&D Biotechne 233-FB), and activin A (R&D Biotechne 338AC050CF), as previously described³⁶.

425 RNA sequencing (RNA-seq)

426 After ensuring read quality via FastQC (v0.11.8), reads were then mapped to the mm10 *Mus musculus*
427 genome (Gencode) using STAR (v2.5.3a), during which we removed duplicates and kept only uniquely
428 mapped reads. Count files were generated by FeatureCounts (Subread v1.5.0), and BAM files were
429 converted to bigwigs using deeptools (v3.1.3) and visualized by the UCSC genome browser. RStudio (v3.6.0)
430 was then used to analyze counts files by DESeq2 (v1.26.0)²² to identify differentially expressed genes
431 (DEGs) with a q-value (p-adjusted via FDR/Benjamini–Hochberg correction) less than 0.1 and a log2 fold
432 change greater than 0.5. For all DESeq2 analyses, log2 fold changes were calculated with IfcShrink using
433 the ashR package⁸⁷. MA-plots were generated by ggpibr (v0.6.0), and Eulerr diagrams were generated by
434 eulerr (v6.1.1). Boxplots and scatterplots were generated by ggpibr (v0.6.0) and ggplot2 (v3.3.2). The Upset
435 plot was generated via the package UpSetR (v1.4.0)⁸⁸. Gene ontology (GO) analyses were performed by
436 the R package enrichPlot (v1.16.2) using the biological processes setting and compareCluster.

437 Chromatin immunoprecipitation followed by DNA sequencing (ChIP-seq)

438 ChIP-seq reads were aligned to mm10 using Bowtie1 (v1.1.2) allowing up to two mismatches. Only
439 uniquely mapped reads were used for analysis. Peaks were called using MACS2 software (v2.2.9.1) using
440 input BAM files for normalization, with filters for a q-value < 0.1 and a fold enrichment > 1. We removed

441 “black-listed” genomic regions that often give aberrant signals. Common peak sets were obtained in R via
442 DiffBind (v3.6.5). In the case of KDM5C ChIP-seq, *Kdm5c*-KO peaks were then subtracted from wild-type
443 samples using bedtools (v2.25.0). Peak proximity to genome annotations was determined by ChIPSeeker
444 (v1.32.1). Gene ontology (GO) analyses were performed by the R package enrichPlot (v1.16.2) using the
445 biological processes setting and compareCluster. Enriched motifs were identified using HOMER⁵⁸. Average
446 binding across the genome was visualized using deeptools (v3.1.3). Bigwigs were visualized using the
447 UCSC genome browser.

448 **Whole genome bisulfite sequencing (WGBS)**

449 Genomic DNA (gDNA) from naïve ESCs and extended EpiLCs was extracted using the Wizard Genomic
450 DNA Purification Kit (Promega A1120), following the instructions for Tissue Culture Cells. gDNA from
451 two wild-types and two *Kdm5c*-KOs of each cell type was sent to Novogene for WGBS using the Illumina
452 NovaSeq X Plus platform and sequenced for 150bp paired-end reads (PE150). - bismark - Methylkit

453 **Data availability**

454 **Published datasets**

455 All published datasets are available at the Gene Expression Omnibus (GEO) <https://www.ncbi.nlm.nih.gov/geo>. Published RNA-seq datasets analyzed in this study included the male wild-type and *Kdm5c*-KO
456 adult amygdala and hippocampus²¹ (available at GEO: GSE127722) and male wild-type and *Kdm5c*-KO
457 EpiLCs⁴¹ (available at GEO: GSE96797).

458 Previously published ChIP-seq experiments included KDM5C in wild-type and *Kdm5c*-KO EpiLCs⁴¹ (avail-
459 able at GEO: GSE96797) and mouse primary neuron cultures (PNCs) from the cortex and hippocampus¹²
460 (available at GEO: GSE61036). ChIP-seq of histone 3 lysine 4 dimethylation in male wild-type and *Kdm5c*-KO
461 EpiLCs⁴¹ is also available at GEO: GSE96797. ChIP-seq of histone 3 lysine 4 trimethylation in wild-type and
462 *Kdm5c*-KO male amygdala²¹ are available at GEO: GSE127817.

650 **Figures and Tables**

- 651 • Supplementary table 1: list of all germline genes.
- 652 – Columns to include:
- 653 * KDM5C bound vs not
- 654 * DEG in EpiLC, brain, both, neither (separate columns?)

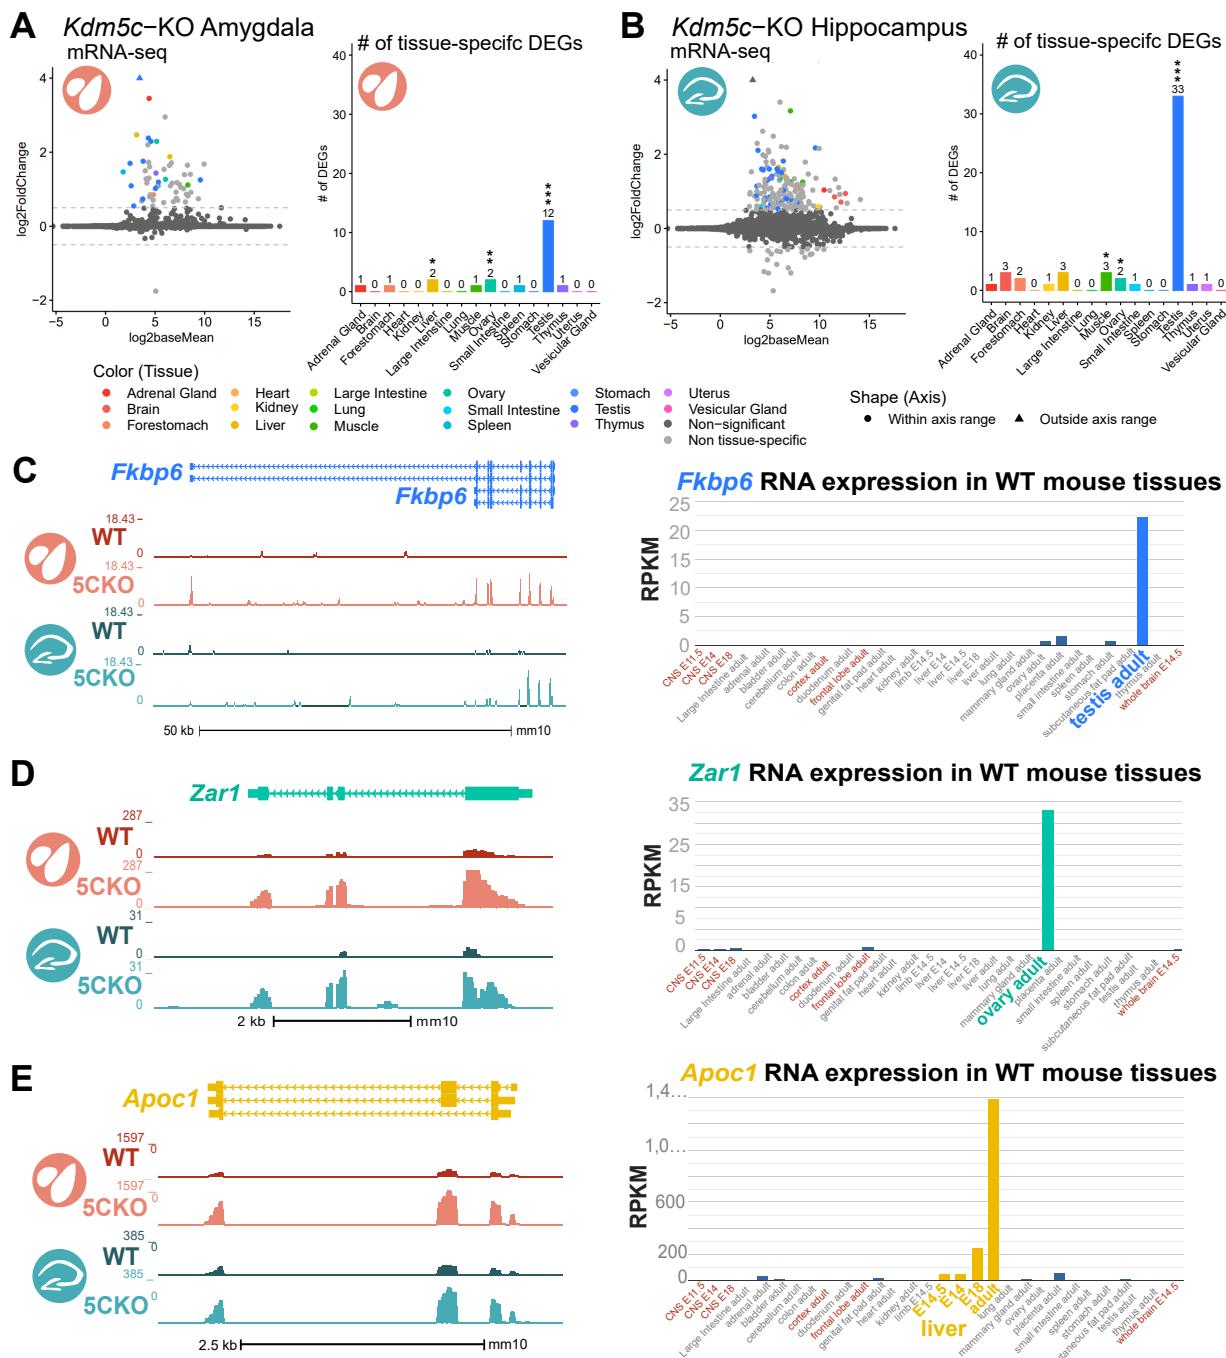

Figure 1: Tissue-enriched genes are misexpressed in the *Kdm5c*-KO brain. **A-B.** Expression of tissue-enriched genes (Li et al 2017) in the male *Kdm5c*-KO amygdala (A) and hippocampus (B). Left - MA plot of mRNA-sequencing. Right - Number of tissue-enriched differentially expressed genes (DEGs). * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, Fisher's exact test. **C.** Left - Average bigwigs of an example aberrantly expressed testis-enriched DEG, *FK506 binding protein 6* (*Fkbp6*) in the wild-type (WT) and *Kdm5c*-KO (5CKO) amygdala (red) and hippocampus (teal). Right - Expression of *Cyct* in wild-type tissues from NCBI Gene, with testis highlighted in blue and brain tissues highlighted in red. **D.** Left - Average bigwigs of an example ovary-enriched DEG, *Zygotic arrest 1* (*Zar1*). Right - Expression of *Zar1* in wild-type tissues from NCBI Gene, with ovary highlighted in teal and brain tissues highlighted in red. **E.** Left - Average bigwigs of an example liver-enriched DEG, *Apolipoprotein C-I* (*Apoc1*). Right - Expression of *Apoc1* in wild-type tissues from NCBI Gene, with liver highlighted in orange and brain tissues highlighted in red.

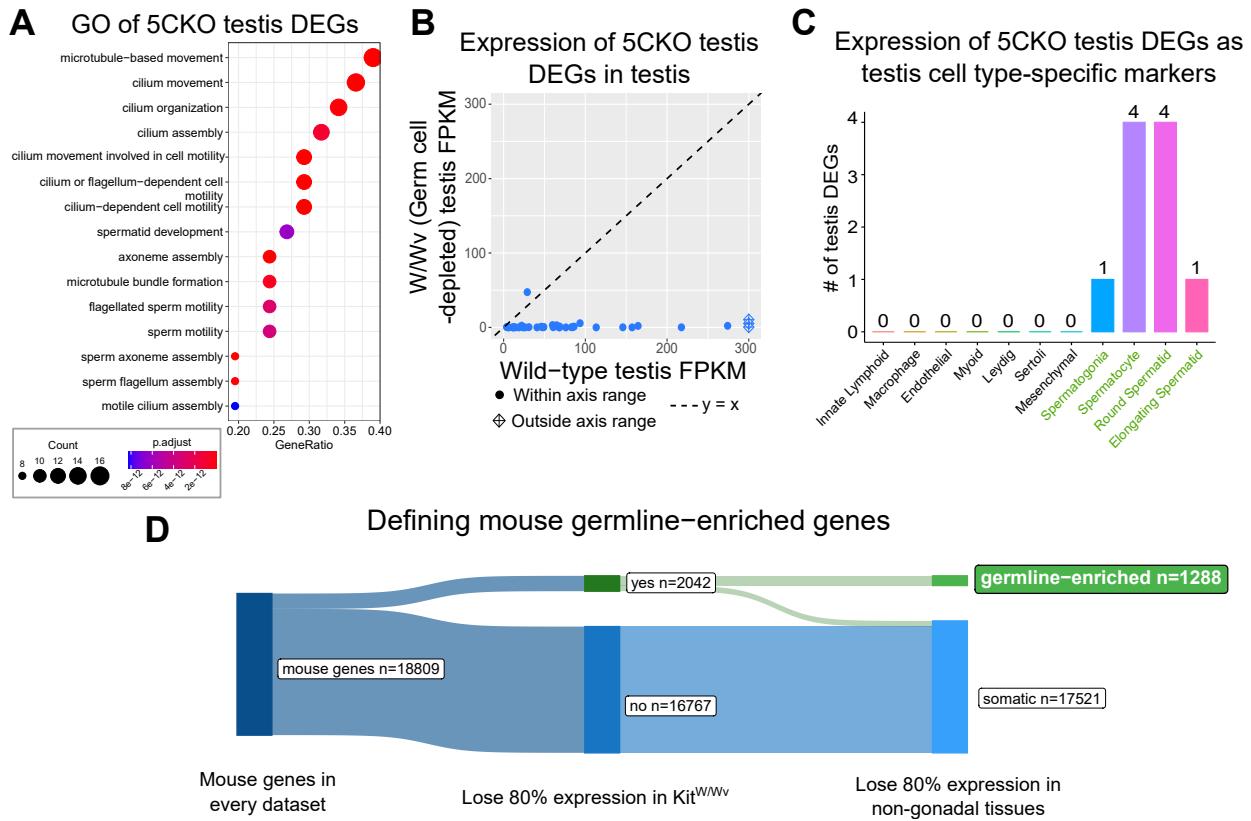

Figure 2: Aberrant transcription of germline genes in the *Kdm5c*-KO in the brain. **A.** enrichPlot gene ontology (GO) of *Kdm5c*-KO amygdala and hippocampus testis-enriched DEGs **B.** Expression of testis DEGs in wild-type (WT) testis versus germ cell-depleted (W/W_v) testis (Mueller et al 2013). Expression is in Fragments Per Kilobase of transcript per Million mapped reads (FPKM). **C.** Number of testis DEGs that were classified as cell-type specific markers in a single cell RNA-seq dataset of the testis (Green et al 2018). Germline cell types are highlighted in green, somatic cell types in black. **D.** Sankey diagram of mouse genes filtered for germline enrichment based on their expression in wild-type and germline-depleted mice and in adult mouse non-gonadal tissues (Li et al 2017).

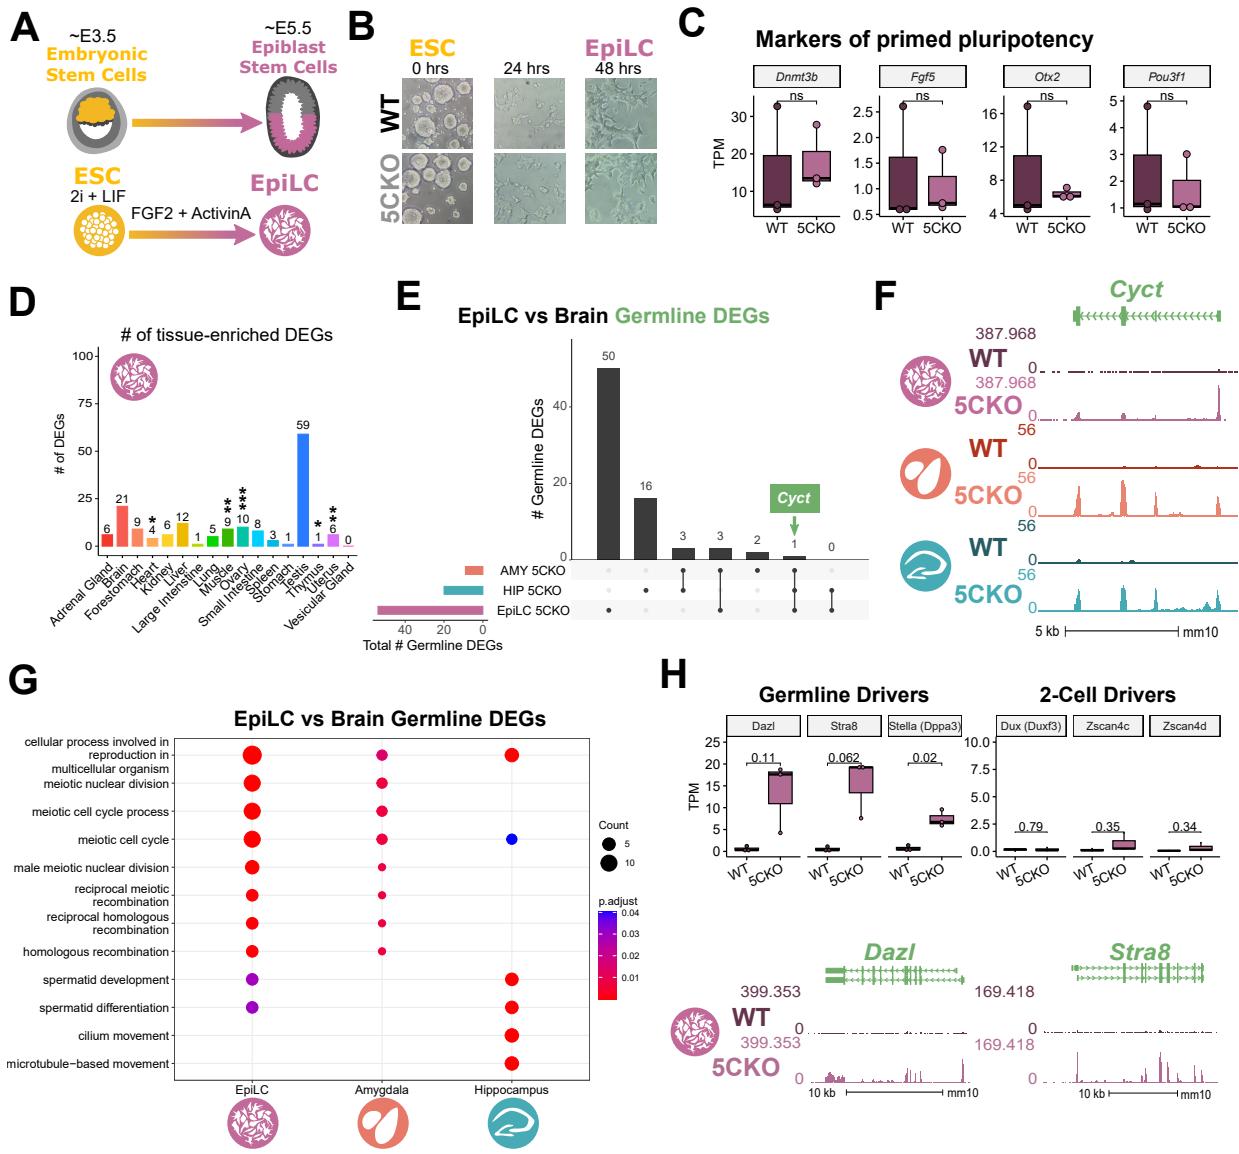

Figure 3: Kdm5c-KO epiblast-like cells express key drivers of germline identity

A. Top - Diagram of *in vivo* differentiation of embryonic stem cells (ESCs) of the inner cell mass into epiblast stem cells. Bottom - *in vitro* differentiation of ESCs into epiblast-like cells (EpiLCs).

B. Number of tissue-enriched differentially expressed genes (DEGs) in *Kdm5c*-KO EpiLCs. * p<0.05, ** p<0.01, *** p<0.001, Fisher's exact test.

C. Average bigwigs of an example germline gene, *Cycl*, that is dysregulated *Kdm5c*-KO EpiLCs. Welch's t-test, expression in transcripts per million (TPM).

D. No significant difference in primed pluripotency marker expression in wild-type versus *Kdm5c*-KO EpiLCs. Welch's t-test, expression in transcripts per million (TPM).

E. Representative images of wild-type (WT) and *Kdm5c*-KO cells during ESC to EpiLC differentiation. Brightfield images taken at 20X.

F. Upset plot displaying the overlap of germline DEGs expressed in *Kdm5c*-KO EpiLCs, amygdala (AMY), and hippocampus (HIP) RNA-seq datasets.

G. enrichPlot comparing enriched biological process gene ontologies for *Kdm5c*-KO EpiLC, amygdala, and hippocampus germline DEGs.

H. Top left - Example germline identity DEGs unique to EpiLCs. Top right - Example 2-cell genes that are not dysregulated in *Kdm5c*-KO EpiLCs. p-values for Welch's t-test. Bottom - Average bigwigs of *Dazl* and *Stra8* expression in wild-type and *Kdm5c*-KO EpiLCs. p-value for Welch's t-test.

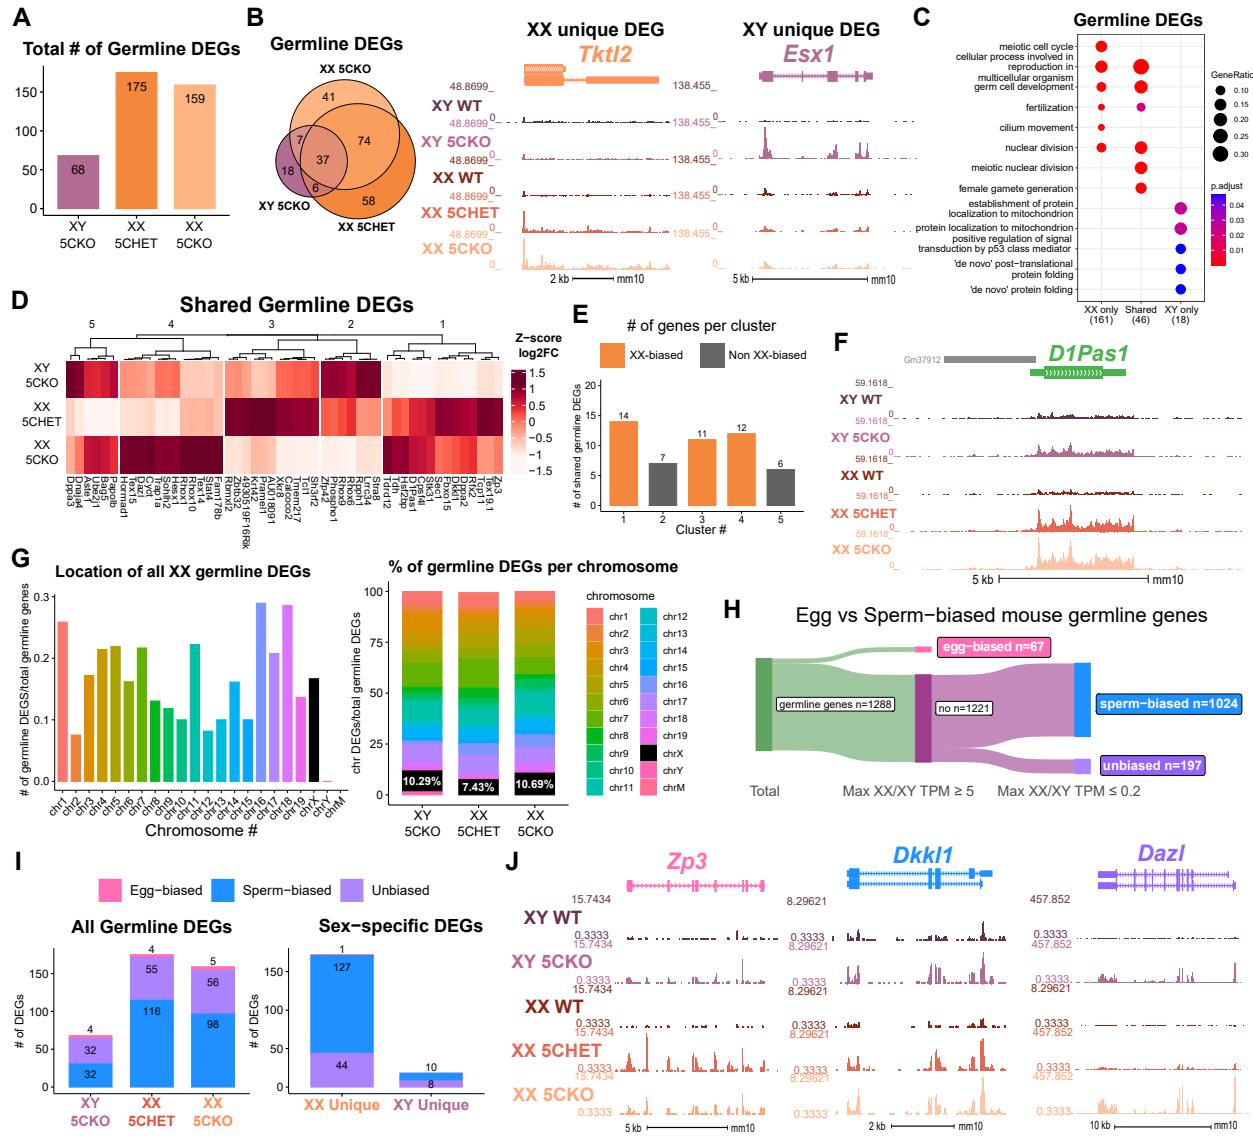

Figure 4: Chromosomal sex influences *Kdm5c*-KO germline gene misexpression. **A-B.** Expression of tissue-enriched genes (Li et al 2017) in the male *Kdm5c*-KO amygdala (A) and hippocampus (B). Left - MA plot of mRNA-sequencing. Right - Number of tissue-enriched differentially expressed genes (DEGs). * $p<0.05$, ** $p<0.01$, *** $p<0.001$, Fisher's exact test. **C.** Left - Average bigwigs of an example aberrantly expressed testis-enriched DEG, *FK506 binding protein 6* (*Fkbp6*) in the wild-type (WT) and *Kdm5c*-KO (5CKO) amygdala (red) and hippocampus (teal). Right - Expression of *Cyct* in wild-type tissues from NCBI Gene, with testis highlighted in blue and brain tissues highlighted in red. **D.** Left - Average bigwigs of an example ovary-enriched DEG, *Zygotic arrest 1* (*Zar1*). Right - Expression of *Zar1* in wild-type tissues from NCBI Gene, with ovary highlighted in teal and brain tissues highlighted in red. **E.** Left - Average bigwigs of an example liver-enriched DEG, *Apolipoprotein C-I* (*Apoc1*). Right - Expression of *Apoc1* in wild-type tissues from NCBI Gene, with liver highlighted in orange and brain tissues highlighted in red.

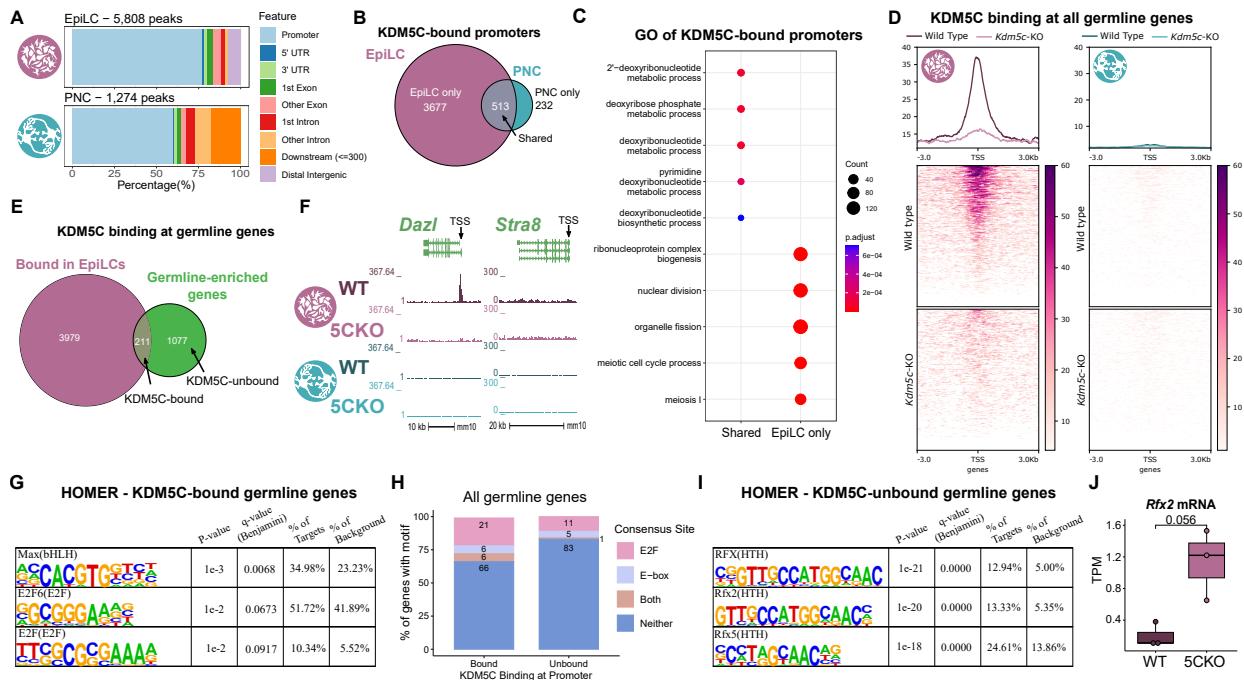

Figure 5: KDM5C binds to a subset of germline gene promoters during early embryogenesis **A.** ChIPseeker localization of KDM5C peaks at different genomic regions in EpiLCs (top) and hippocampal and cortex primary neuron cultures (PNCs, bottom). **B.** Overlap of genes with KDM5C bound to their promoters in EpiLCs (purple) and PNCs (blue). **C.** Gene ontology (GO) comparison of genes with KDM5C bound to their promoter in EpiLCs and PNCs. Genes were classified as either bound in EpiLCs only (EpiLC only), unique to PNCs (PNC only, no significant ontologies) or bound in both PNCs and EpiLCs (shared). **D.** Average KDM5C binding around the transcription start site (TSS) of all germline-enriched genes in EpiLCs (left) and PNCs (right). **E.** KDM5C binding at the promoters of RNA-seq germline DEGs. Genes were classified as either only dysregulated in EpiLCs (EpiLC only), genes dysregulated in the hippocampus or amygdala but not EpiLCs (brain only), or genes dysregulated in both EpiLCs and the brain (common). (Legend continued on next page.)

Figure 5: KDM5C binds to a subset of germline gene promoters during early embryogenesis. (Legend continued.) **F.** Example KDM5C ChIP-seq bigwigs of DEGs unique to EpiLCs. Although both are expressed in *Kdm5c*-KO EpiLCs, KDM5C is only bound to the *Dazl* promoter and not the *Stra8* promoter in EpiLCs. **G.** Example KDM5C ChIP-seq bigwigs of RNA-seq DEGs common between the brain and EpiLCs. KDM5C is bound to the *D1Pas1* promoter but not the *XXX* promoter in EpiLCs. **H.** Example KDM5C ChIP-seq bigwigs of RNA-seq DEGs unique to the brain. KDM5C is bound to the *XXX* promoter but not the *Meig1* promoter

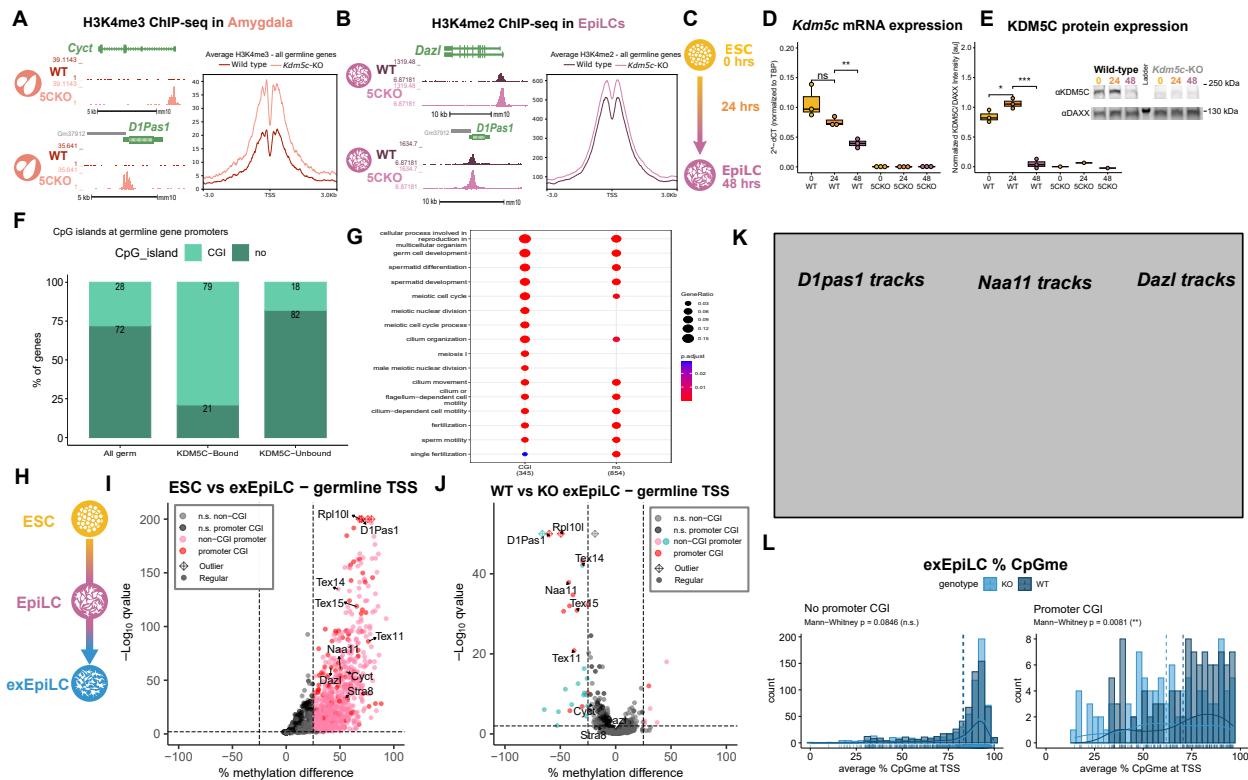

Figure 6: KDM5C's catalytic activity promotes long-term silencing of germline genes via DNA methylation. **A.** Left - Bigwigs of representative histone 3 lysine 4 trimethylation (H3K4me3) ChIP-seq peaks at two germline genes in the wild-type (WT) and *Kdm5c*-KO (5CKO) adult amygdala. Right - Average H3K4me3 at the transcription start site (TSS) of all germline-enriched genes in wild-type (dark red) and *Kdm5c*-KO (light red) amygdala. **B.** Left - Bigwigs of representative histone 3 lysine 4 dimethylation (H3K4me2) ChIP-seq peaks at representative germline genes in wild-type and *Kdm5c*-KO EpiLCs. Right - Average H3K4me2 at the TSS of all germline-enriched genes in wild-type (dark purple) and *Kdm5c*-KO (light purple) EpiLCs. **C.** Diagram of embryonic stem cell (ESC) to epiblast-like cell (EpiLC) differentiation protocol and collection time points for RNA and protein. **D.** Real time quantitative PCR (RT-qPCR) of *Kdm5c* RNA expression, calculated in comparison to TBP expression ($2^{-\Delta\Delta CT}$). * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, Welch's t-test. **E.** KDM5C protein expression normalized to DAXX. Quantified intensity using ImageJ (artificial units - au). Right - representative lanes of Western blot for KDM5C and DAXX. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, Welch's t-test **F.** XXX **G.** XXX
